Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

An Explanation Wanted

The Editor:

Sir—I write the following description of cyaniding a small lot of tailing at the McCabe mine, Riverside county, California, in hope that some one may be able to throw light on the subject. It would be of benefit to those interested in cyaniding situated as I have been in an out-of-the-way place and operating in a small way. While I am familiar with the ordinary cyanide process, having been employed from time to time as a solution-man, I am not a chemist or cyanide expert. I hope that the following account of the successful treatment of this material, after I had made a failure of straight leaching, may be of sufficient interest to some chemist to cause him to give a clear explanation of the process. I would like also to learn to whom credit is due for introducing the method in practice.

The tailing was crushed by stamps until it would all pass a 24-mesh screen. About one-third of the total tonnage was slime, which was run to a separate pond. After cultivating and rolling the slime to pulverize it, I mixed one ton of slime with two of sand while filling the vats by hand shoveling, using scrapers to bring the material to the shovelers. I had no trouble with percolation at any time. The leaching was done in tanks 4 ft. deep and 12 in diameter. My early runs, which proved failures, were under ordinary conditions, using strong and weak solutions alternately and precipitating on zinc shaving. In these runs I used cyanide solutions of 0.15 to 0.40% strong, equivalent to 3 to 8 lb. of cyanide per ton of water, and used on average 3 lb. of lime per ton of tailing to neutralize the acidity. The extraction made by the different solutions in any run was never better than 35% of the assay-value of the heads. After repeated and disheartening failures, I gave up the treatment. I then submitted samples to a chemist for analysis with the following results as far as metallic contents were concerned: arsenical sulphide, 3%; zinc-blende, 1.5%; lead, less than 1%; antimony and silver, traces; gold, 0.32 oz. per ton. I submitted this to an expert who teaches cyaniding and was advised to quit, pocket my loss, and look pleasant. About a year later I met a fellow solution-man in Los Angeles who at one time had been employed in the northern part of the State, where he assured me ore similar in character was being successfully treated. He was unable to give me the address, or the men in charge were unwilling to bother with answering my frantic requests for help; at any rate, I received no information except that gleaned from my chance acquaintance, which was very little. It was about as follows: To the solutions used, potassium acetate was added in the proportion of 1 lb. acetate to 5 lb. potassium cyanide. The same proportions were used when bringing a solution up to standard. Lead oxide and shavings were used in the first compartment of the precipitating box. He assured me that in some manner the acetate in the solution, combined with the lead, caused a perfect precipitation of gold from complex or fouled solutions. After studying the matter for several weeks I decided to try again. My tests gave satisfactory results and solved what was to me a very difficult problem.

I made up my solutions and dressed my zinc-boxes as directed, and proceeded with my first run, using a single standard solution of 5 lb. KCy with 1 lb. acetate for the first or saturating solution. This was followed with a 2-lb. solution, the weak and strong solutions following alternately for 96 hours, when the vat was drained and wash-water introduced until the bulk of solution was again normal, when the charge was practically dry. Holes were bored with a tryer over the surface of the charge and the resultant sample dried and assayed with the, to me, astonishing result of 94% extraction. I then made assays on the sump solutions which proved to contain less than 20 cents per ton in gold. As the original tailing being treated averaged more than $6 per ton, this recovery was satisfactory. During the succeeding runs, I had no trouble either in leaching or precipitating. Since, however, everything connected with the operation is strange and past understanding to me I will go a little further into detail in regard to precipitation. I made repeated assays on the gold-bearing solutions in the zinc-boxes and found that little gold passed below the fourth compartment, and the most peculiar thing was the action or condition of the zinc shavings in the upper baskets. The sponge remained porous as ever, but after a few days' run became soft and velvety and at a touch would go to slime, the zinc having lost its spring or wire-like character. Still the precipitation seemed to be perfect, and on the final clean-up the total recovery of bullion was more than 90% of the assay-value of the material in the tanks as filled. The bullion melts assayed above $15 per ounce. I can not attempt to explain anything other than that described above, but have learned that several plants in California and Nevada use this method as a whole or in part, and would be pleased to have some of the chemists in charge make some of the dark places light, and tell why I successfully treated this sand, or give a description of plants that use the process.

Los Angeles, October 31.

Inhalation of Mineral Dust

The Editor:

Sir—Replying to 'Drill Runner's' query regarding 'Inhalation of Mineral Dust,' which appeared in your issue of October 15, the following explanation will probably cover the majority of cases. Underground, the dust from machine drills is to a considerable extent composed of sharp chips or cuttings of quartz and other silicified rocks. In the majority of cases the cuttings fall from 'uppers' and the sharp par-

ticles of rock drop away from the drill bit without being further pulverized. In the few cases where the rock is soft and free from quartz stringers the dust is much more finely divided, and moreover seldom has any serious effect on the drill runners. In the dry-crushing mill, on the other hand, the prevalent dust is produced from the soft 'taley' portion of the ore, which is reduced to an impalpable powder during the process of reducing the harder and more silicious portion of the ore. This latter material is finally reduced to a granular product approaching sand of varying degrees of fineness. Even after continued grinding or stamping these particles will settle almost immediately in air and will therefore not produce the impalpable powder which forms the bulk of dust noticed in a dry-crushing mill.

Hardening and Tempering Drill Steel

The Editor:

Sir—Having had difficulties similar to Mr. MacDonald's, I read with interest his letter regarding the hardening and tempering of drill steel in your issue of October 22. After having observed the methods of many tool sharpeners, good, bad, and indifferent, in various parts of the country, I have come to the conclusion that good mine blacksmiths are hard to find, but that when one is found he can always, after a trial or two, make good drills. The method noted below differs from that given by Mr. MacDonald and may be of interest.

Hammer checks are usually caused by forging too cold; ordinary steel should not be worked below a medium red heat, although it does no harm to finish the cutting edge with light blows at a dull red. In shaping the bit, hammer toward the shank as much as possible; that is, do not draw it out any more than is absolutely necessary. After sharpening it is very important to allow the drills to cool. This permits any molecular strains caused by the forging to adjust themselves: if the steel is hardened without being thus annealed it is extremely likely to crack. When reheating for the purpose of hardening, the steel should never be heated enough for scales to form on the surface. If a piece does accidentally get so hot that scales form, it should be allowed to cool thoroughly and be heated again. When plunging, if the surface of the water is kept at the same point on the steel all the time the point or edge of the tool is under water, a crack is apt to develop at that point. For this reason it is best to plunge the tool deep into the water and so prevent the formation of a sharp surface between the soft shank and the hard edge. The slower the heat runs down when the temper is being drawn, the better. The tempering water should not be allowed to become hot. There is considerable difference of opinion among blacksmiths as to the effects of the water used in different localities on the tempering of drills. Some advocate the use of salt, sal ammoniac, or other 'dopes' in the tempering water; some say that different waters require different heats; others say that the water makes no difference whatever. My own observations lead me to believe that it makes little, if any, difference where, as is generally the case, the water is reasonably pure.

Tin Smelting

The Editor:

Sir—Can you or some of your readers tell me the composition of the block tin that reaches the refining works at Swansea? I understand that the concentrate is smelted in Cornwall and the product shipped to Swansea for further refinement. What is now done with this product at the Swansea tin-plate works? Why are the works situated at Swansea instead of some convenient place in Cornwall where the tin is largely produced? Are there any tin-plate works in America similar to the one at Swansea?

George H. Carter.

Rawhide, Nevada, October 26.

[In tin smelting, as in treatment of lead and copper ores, proximity to the mine is not always the first consideration. In order to operate economically, mixtures of ore are necessary. In Cornwall the concentrate produced locally is mixed with richer Bolivian ore to which is added culm, slaked lime, fluorspar, and occasionally slag or other products of previous operations. The work carried on locally is the production of block tin. This can be accomplished in small and cheaply constructed furnaces just as copper matte can be produced in a relatively cheap plant. The block tin, like the matte, must be refined, and refineries are generally established at points determined by favorable transportation facilities and nearness to markets rather than in the vicinity of mines. For much the same reason that base bullion and blister copper in the United States are generally sent East to be treated, block tin goes to Swansea and other points for refining. In both cases there are advantages on the side of established works operated by experienced men. The United States produces but little tin ore and the smelters operating here are de-tinning establishments engaged in re-melting scrap. Small reverberatories for treatment of ore have been operated in California and in other States, but so far as we know all are now closed. We do not have at hand analyses of the block tin before refining. The impurities, however, include iron, copper, lead, antimony, and arsenic, which alloy with tin at the high temperature necessary in reduction of tin oxide.—Editor.]

Reinforced concrete is considered superior to almost every other material for building with a view to resisting earthquake shock. The only building that did not sustain severe loss at Stanford University at Palo Alto, California, from the earthquake of April 18, 1906, was a structure of concrete—the museum. It was built nearly 20 years ago, when the art of constructing reinforced concrete buildings was not as well understood as at present.

Special Correspondence

WASHINGTON, D. C.

Conference of Mining Engineers.—West Virginia Decreases Accidents. —Projected Alaska Legislation. — Coal Lands Restored to Entry. —Land Office and Forest Service.

The conference of the mining engineers connected with the Bureau of Mines closed with a dinner at the Fort Pitt hotel, October 29, and the men scattered to take up their regular work with the new mine-rescue cars. Car No. 1, in charge of Charles Enzian, left for Monongahela City, Pa., where the first demonstration of rescue apparatus and lecture were given. This car will visit Marianna, Brownsville, Uniontown, Connellsville, Scottdale, Indiana, Johnstown, Windber, South Fork, Portage, Cresson, Punxsutawney, Clearfield, Philipsburg, and State College in the bituminous fields of Pennsylvania. Car No. 2, in charge of R. Y. Williams, left for work in Indiana, Illinois, and Kentucky. No. 3, J. C. Roberts in charge, will travel in Colorado and New Mexico. No. 4, with Mr. Wolfiin as engineer, will cover the northern territory from Montana west. No. 5, J. J. Rutledge in charge, is already at work in the coalfields of West Virginia, Kentucky, and Tennessee. No. 6, in charge of Sumner S. Smith, will soon be sent to Wyoming and Utah. A seventh car will be held in reserve at the Pittsburg station to answer calls in western Pennsylvania and Ohio. Among accidents recently investigated by the engineers was one in which an explosion occurred when no one was in the mine. Evidently the 'careless miner' was not to blame in this case, unless he neglected to extinguish a burning blower.

That the work of the Technologic Branch of the Geological Survey, now the Bureau of Mines, is beginning to bear fruit was evidenced recently in a statement issued by Mr. Laing, Chief Mine Inspector West Virginia. He said that in the last seventeen months, not a single man had lost his life in the coal mines of West Virginia through the explosion of gas or coal dust. In the year before, more than 100 were killed in such explosions. J. A. Holmes, director of the new work, early warned against the use of any but the short-flame permissible explosives in dangerous mines. This was made a rule in West Virginia and none but 'permissible explosives' bearing the stamp of approval of the Government may be used in those mines. Warnings against the dangers of coal dust were also issued, and the mine owners of West Virginia, at the suggestion of Mr. Laing, took precautions against the accumulation of coal dust, evidently to some purpose.

It is expected that there will be important legislation this winter affecting Alaska. George W. Wickersham, attorney general, and Charles Nagel, Secretary of the Department of Commerce and Labor, spent the summer in Alaska at the instigation of Mr. Taft. They went carefully over the field and held conferences with every man of any prominence. Their report on what is necessary to aid in the development of the mineral resources of Alaska is now in the hands of the President. He will undoubtedly outline his views on this important problem in his annual message to Congress when it convenes in December. Messrs. Wickersham and Nagel refuse to discuss the results of their trip to the North, with the exception of remarking that something should be done by Congress at once to open up Alaska. Several weeks ago the Interior Department promulgated an order throwing open to agricultural entry 900,000 acres of land withdrawn as being valuable as coal lands. The opening of these lands was accomplished under a recent act, one of the administration conservation measures, providing for the agricultural entry of the surface of public coal lands, the coal deposits being reserved for separate disposition. The West should be exceedingly benefited by the measure, according to the officials of the Department of the Interior, permitting, as it does, a twofold exploitation—the use of the surface for crop raising and the separate use of the coal. The act does not apply to Alaska.

Charles Mindeleff, of New York, an expert metallurgist, has been appointed by the Treasury Department to visit all the mints and report suggestions for economies and improvements in the processes of weighing, assaying, melting, and refining. To promote co-operation between the field officials of the General Land Office and the Forest Service in the settlement of claims for homestead settlement within the National Forests, representatives of the Interior and Agricultural departments have left Washington for the West to confer with the field agents of these two branches of the Government. The task has been delegated to James M. Sheridan, chief of the field division of the General Land Office; D. D. Bronson, of the Forest Service, and R. W. Williams Jr., assistant to the solicitor of the Department of Agriculture. The purpose is to make settlement of claims between the Government and the public easier for the latter.

LONDON

Interesting Magnetic-Concentration Process. — Remarkable Copper Mine in Chile.—The Caucasus Copper Company.

Interest has been revived this week in the Murex magnetic concentration process by the issue of official information as to the progress of operations of the company owning this process. *The Mining Magazine*, in October a year ago, published a statement relating to the claims of the inventor, A. A. Lockwood, and of the directors of the company. Briefly the process consists of adding magnetite or other magnetic mineral to sulphide ore together with sulphate of alumina and some oily substance and removing the agglomerated magnetite and sulphide by means of magnets. A plant was first erected at the Cordoba copper mine in Spain; this is doing well on all classes of ore and dump material, and an additional unit has been ordered. The plant erected at the Broken Hill, Block 14 mine, has not progressed so rapidly, partly owing to the illness of the engineer who was sent out, and partly because the old plant available for use was not easily adapted to the process. The latest cable shows that the engineer in charge sent 73 tons of Broken Hill ore, as it comes from the mine, through the machine in 30 hours, and that the tailing contained only ½% zinc, 2% lead, and 1.9 oz. silver. It is announced that Mr. Lockwood is to go to Broken Hill shortly. Arrangements were made with Alexander Hill & Stewart to erect a plant at the Van Roi mine, British Columbia; this arrangement was subsequently modified by building the plant at a smelter in that country so that mining engineers and metallurgists wishing to inspect the process might have easier access to it. A plant is being sent to a silver mine in Bolivia belonging to Aramayo & Co., and another to the Malines zinc-lead mine in France. It is also reported that a contract has been made to treat an ore consisting of blende and magnetite found at the Cristoff mine, Germany. These last three plants, as well as that at Cordoba, have been supplied on a royalty basis. The directors report that patents have been obtained in every country without difficulty, and that no opposition to them has so far appeared. The capital of the company is £120,000, of which £89,217 went for purchase of patent rights; about £25,000 has been spent on plant, experimental work, and administration; and about £7000 remains. The directors expect to be drawing an income from royalties before long. People often ask the meaning of the word 'Murex.' It is Latin for a 'shell,' and Mr. Samuel, one of Mr. Lockwood's financial supporters, belongs to the family of Samuels that controls the Shell Transport & Trading Co., which is now known in America as the powerful rival of the Standard Oil Co. in the East.

The Poderosa Mining Company, Ltd., was formed in November 1908 to acquire a group of copper mines in the Collahuasi district, Chile, at an altitude of 15,000 ft., belonging to a local company called the Compania Minera Poderosa de Collahuasi. The first manager was Robert Hawxhurst, Jr., of San Francisco, but he did not remain long owing to disagreement with the board. Several of the directors retired at the same time and the board was reconstituted. C. H. Macnutt is now manager, and W. J.

Barnett, consulting engineer and also a director. The report of the company covering the year 1909 was not issued to the press or public, and the meeting of shareholders was held privately, so I have only recently received the report in question. The capital of the company is £500,000 in 100,000 shares of £5 each, and there are £50,000 debentures. During the year 1909, 25,782 tons of ore was sold to the smelters abroad through the port of Mejillones averaging 22% copper and 6½ oz. silver, and the amount realized was £181,211. The cost of mining has been greater than was expected and amounted to £188,253, of which the transport by rail amounted to no less than £40,489. In addition, management in London and at the mine cost £16,945, mine development £7487, and £6069 was allowed for depreciation. The net loss for the year was £40,814, to which has to be added £26,458, an interim dividend paid in July by the former directors, making the total adverse balance for the year £67,272. This distribution of dividend was due to an error of judgment on the part of the board, who only had a vague idea of what the cost of mining would be. The report now issued is a composite one. The work during the first half of 1909 is described by Mr. Hawxhurst and during the second half by Mr. Macnutt, while Mr. Barnett gives a general account of the mining operations. The shipments during the first half of the year were 12,909 tons averaging 24½% copper and 7.8 oz. silver, and during the second half 13,404 tons averaging 20% copper and 5½ oz. silver. In addition to this shipping ore, about an equal amount of ore was sorted out and placed on the dumps to await further treatment; the average content of this was 6% copper. The largest proportion of ore came from the Poderosa mine, about 20% came from the San Carlos, and a small amount from the Rosario. On December 31 the reserve at the Poderosa was 20,000 tons of developed ore averaging 21%, and 7000 tons of probable ore. The dumps at the three mines contain 64,800 tons averaging 5.6% copper. I may add here that the monthly reports now published show an increasing output, the figures for September being 2392 tons assaying 22% copper. As regards smelting on the spot, Mr. Barnett reports adversely. In the first place there is an excess of silica and no suitable flux is found near-by; secondly the cost of carrying coke to the mine is high; and third, the ore reserves are not sufficiently great to warrant the capital expenditure. On other points he speaks hopefully of the prospects of the property.

The Caucasus Copper Co. was formed in 1900 to acquire the Dzansul copper mine in the Russian Caucasus. Several high-class mercantile firms in London hold the shares, and a large interest is in the hands of the J. P. Morgan group. The ore is plentiful, of low-grade, and difficult to concentrate. The first attempt at treatment was by direct smelting, but so large an amount of flux had to be added that the copper content of the furnace charge was unprofitably low. Subsequently dry magnetic concentration was tried without success. Two years ago James Colquhoun, the former manager of the Arizona Copper Co., joined the board and undertook the study of the concentration problem. The new plant is giving satisfaction, and is now treating 500 tons of ore per day. The monthly production of concentrate is now sufficient to yield 200 tons of copper in the smelter. The directors have decided to increase the capacity by another 250 tons and later to bring the total capacity to 1000 tons per day. During the year ended May 31, the production of copper was 1140 tons and the loss on operations was £27,590. In addition £48,840 was spent on new plant, and £99,320 was written off for depreciated plant. The roasting furnaces at present in use are not sufficient to treat the output, and two new furnaces are being erected. The supply of power is being increased by passing the gases from the reverberatories through water-tube boilers. The smelting department has been for seven years in the hands of W. R. Van Llew, who has recently been appointed general manager of the company. The amount of money spent in this venture has been great, as may be seen by an inspection of the balance-sheet. The capital is £500,000, there are £636,000 debentures, and £459,900 has been advanced on loan

ST. PETERSBURG, RUSSIA

Number of Dredges at Work. — Improvement Over Preceding Years.

The annual report of the work done in the year 1909 by gold dredges in the Russian and Siberian goldfields has just appeared, and from most points of view may be called a satisfactory statement, if for no other reason than that the yield per dredge shows an increase over the results obtained in past years. Dredging is practically a new method of winning gold in Russia, and although something like 60 dredges are working here, they cannot be said to be operated with the expert experience that is required to get the best out of them. Nevertheless, from results obtained, one of two conclusions must be reached—either that the Russian dredge superintendent has learned to do his work well, or he has learned where to take his dredge. It is difficult, if not impossible, to identify the various dredges. Some have been obtained from America, some from England, and some from the Dutch dredge-building yards, but a relatively large number have been built in Russia. The place where most of the Russian dredges are made is the Putiloff (Russia's premier engineering works). Another large concern that used to build many dredges is the Neviansky Works, but, probably because dredge building was not sufficiently remunerative, it has discontinued the construction of new dredges and limits its operations to the repair of old ones. This is likewise a gold mining firm and it exploits certain alluvial deposits. But with the disappearance of the Neviansky Works as a dredge maker, the Sormoff Engine Works has entered the field of dredge building. It has probably come into existence under protection of the country's tariff, which is very heavy on all manner of shipbuilding. About a year ago the customs exemption period of ten years which had been established in favor of foreign dredges, expired and all the efforts (and they were great and persistent) on the part of the Russian gold producers failed to move the Government from the position it had taken, namely, to allow the exemption to lapse. The consequence is that as the Government did not renew the exemption, the heavy tax operates to the practical exclusion of the foreign dredge builder. That will account for the special efforts of the Sormoff company.

The dredge of the Bogosloff company was constructed by the Neviansk foundry, and dredge No. 10 of the Zauralsk Mining Co. was built by the Putiloff foundry, which also constructed the dredge operating at the Verchne-Tailinsk gold mines of the Altai Gold Concession Co. after the Bucyrus type. Several of the alluvial deposits are worked by dredges of the New Zealand type, and are constructed by the Korobelnikoff foundry in the Urals, the machinery being made in England. The New Zealand system is likewise employed at the Kungursk mines and at the Elizabetinsky mine and a Dutch dredge is working in the Severnaya Talga goldfields. The method adopted for collecting information relative to the work of the dredges was the customary one of issuing question blanks and requesting replies to be written thereon. As might be expected, a number failed to answer at all, others did not fill out the blanks; but gave their reasons for refraining from giving details. The total number of dredges for which returns were given was 48. The returns include the period during which the dredge worked; the capacity, the number of working days actually operated; the quantity of material dredged, and the amount of gold and platinum recovered. Quoting from returns for 1909, it is found that in Russia and Siberia the 48 dredges raised 603,352.6 cubic sazhens of ground or sand in 113,634 working hours, and the gold and platinum washed therefrom make a total of 77,378 oz., an average of about 14,715.92 cubic sazhens per dredge out of 41 dredges, and 1812 oz. per dredge. The number of dredges reported to have been at work over the area referred to in 1909 was 55, which is somewhat less than those working the preceding year. This is accounted for by the fact that several large houses, notably the Draga company. The Phedoroffsky company, and the Neviansk company, did not work so many dredges in 1909.

An analysis of the tabulated statement shows that the

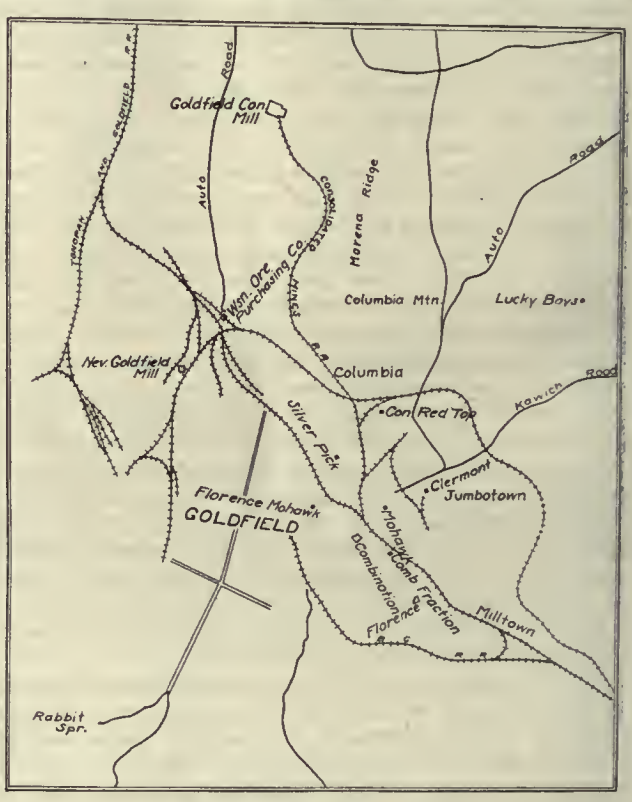
average quantity of material handled during 1909 was an increase of 12.4% over that of the previous year, while the average production showed an increase of 26%. It is interesting to note that the increase in the percentage of gold was nearly twice the increase in yardage handled. From this it is concluded that the operators are using discriminating judgment in the selection of dredging ground. The average content of gold per cubic yard increased in 1909 to 0.123 oz. from 0.109 oz. in 1908.

There is no doubt that dredging will increase over practically the whole area, excepting perhaps the Urals, where the sands have been worked with such persistency that the great preponderance of alluvial gold over vein gold is being rapidly lessened, and those who would work the Urals thoroughly must be content to engage in vein mining. In Siberia, however, no such necessity exists. The gold produced over that vast area, both by hand and machine, including dredges and excavators, is well over 90% from alluvium, so that the future of gold mining there may be said to rest with dredging. Of course it must not be supposed that this statement covers all the gold industries, either deep mining or alluvial, in Russia and Siberia. It deals only with dredge work. There are districts of which no mention is made in the report where excavators, but not dredges, are at work.

GOLDFIELD, NEVADA

Goldfield Consolidated Dividends and Quarterly Report.—Important New Developments.

Dividend No. 9 (regular quarterly of 30c.) of the Goldfield Consolidated Mines Co. was paid to stockholders October 31, and an extra of 20c., being the fourth consecutive quarterly distribution of 50c. per share on the 3,559,148 shares of the company's stock outstanding. Stockholders were also supplied with a statement compiled by J. R. Finlay, the manager, and attested by A. H. Howe, secretary and treasurer of the company, setting forth the production and earnings for the second quarter of the fiscal year. The report made by the manager, covering the quarter ended September 30, shows a total of 70,193 dry tons treated and shipped, the gross value of which was $2,607,852.96. Operating costs for the quarter were $587,822.45, construction $75,000, metallurgical losses $161,968.79, total costs and losses $824,791.24, and net profits $1,783,061.72. The last figure exceeds the amount of the dividend by over $3000. Figures for September were approximate, as settlement for bullion at the mint was not complete, but there will be little variance from these totals. On September 30, as shown in the report, the company's cash balance aggregated $2,558,340.80, and on October 31, after the payment of dividend No. 9, the cash balance was approximately $1,400,000. A comparatively small amount of ore was shipped to smelters during the quarter and all mill products were treated in the company's refinery. The mill is again operating at full capacity of over 850 tons per day, and the company still has a large tonnage of high-grade smelting ore available which can be drawn upon for shipments in the event of its being required to supplement the bullion production of the mill. Development on the 1000-ft. level of the Clermont has produced results during the past fortnight which are regarded by the management as among the most important in the history of these mines. An ore-shoot was penetrated about a month ago on this level, some distance to the southwest of the original discovery of ore at this depth, and for a distance of 35 ft. the ore was of excellent grade, after which the drift ran in material too low grade to treat profitably, then again entered an orebody of gratifying size and value. The drift has progressed 65 ft. in ore said to average $60 per ton, and containing seams of higher grade ore, some of the latter yielding assays of $500 per ton. The orebody is 20 ft. wide at one point. This ore-shoot is thought to be the downward extension of the Mohawk shoot, which has yielded a great quantity of high-grade ore above the 600-ft. level, and particularly from the famous '403' stopes, near the southeast boundary of the Mohawk claim. The vein dips east, toward the new workings, and in character the ore resembles that of the Mohawk rather than the general run of Clermont ore, containing much free gold in quartz boulders and breccia surrounded by talc and pyrite, and carrying but little antimony, copper, or bismuth. The new hoisting engines, of large capacity and electrically driven, will soon be in operation at the Clermont, Mohawk, and Laguna shafts, and all new construction work is rapidly nearing completion, including the storage-battery plant, electrically-operated machine shops, transformer houses, heating plant, and refinery. With the completion of this work a large item of monthly expense will be eliminated, many important factors for economy in operation will be put in effect, and the company's net earnings will be correspondingly enhanced. From officials of the Combination Fraction Mining Co. it is learned that the company is making profit on the 50 tons of ore treated daily at the leased Nevada Goldfield mill of 20 stamps. Good progress is being made in sinking the main shaft of the Florence Goldfield Co., recently enlarged by raising from the bottom, 530 ft. deep, to the surface. Machine-drills are in use and



Goldfield and Vicinity.

stations will be cut at intervals with pockets for ore and waste. The latter will be hoisted to the upper levels and used in filling. Automatic skips, operating in balance, will shortly be in use and will be of 3-tons capacity each. The ore of the Florence for some time past has been low grade and an effort has been made to clean up everything from the old lease workings from which a profit could be recovered. Some ore of better grade has been coming from the vein opened on the 350-ft. level north of the main workings and near the old bonanza Reilly lease. Stopes are being opened in this vein for 300 ft. and there is promise of a large tonnage of milling ore of medium grade. New levels will be started from the main shaft below the 500-ft. point, driving for orebodies that have yielded a good production above that level. Two carload shipments have been made from the Nevada Eagle, situated three miles west of Goldfield, and an orebody is being developed in a raise above the 250-ft. level from the 400-ft. shaft. A mile north of the Nevada Eagle and in similar formation, the Nevada Victor is driving on a promising vein. The Grizzly Bear Co., operating a lease on Consolidated ground, has resumed work on the 1170-ft. level from its 1200-ft. shaft, the deepest in the district. The lease expires February 1 next and the Consolidated company has refused a renewal, but recent discoveries on the 1000-ft. level of the Clermont, near

the leasing company's territory, has stimulated the latter to endeavor to find the same ore-shoot in its 1170-ft. workings. Several applications have been made for leases on the claims of the Diamondfield Black Butte company, where one lessee has been taking out ore of shipping grade from old workings near the Bonanza Flat vein. Five lessees continue operations on the Atlanta, the Precious Metals Co. driving on the 730-ft. level and the Queen Consolidated Co. exploring the vein from which the old Cherokee lease obtained good assays at a depth of 540 ft. One lease is working on the Sunflower claim of the Merger Mines Co. and is seeking the vein from which high-grade ore was taken and shipped by the Ford lease near by. The Manning lease on the Goldfield Oro is prospecting near the surface and sinking the old Oro shaft to greater depth.

MEXICO

Railroad Extensions Contemplated.—Important Consolidation. — New Hydro-Electric Power Plants.

Much construction work is planned by the National Railways of Mexico, and it is expected to add 2000 kilometres of new track to the mileage of the government merger system within the next few years. The lines projected will open rich territory, and several mineral districts will be benefited. One of the roads included in the program is that planned to extend from Gutierrez, on the Mexican

Magistral Mine, Ameca District, Jalisco.

Central main line, through Zacatecas and Durango to the City of Durango, about 155 miles, and the line will serve the Sombrerete, Chalchihuites and Nieves mining districts of Zacatecas, and the Nombre de Dios district of Durango. Subsidies have been granted by the governments of Zacatecas and Durango, and some financial assistance will be given by private interests in view of transportation benefits. Work has been commenced on a line from Penjamo, a station on the Guadalajara division, south through the State of Michoacan to a connection with the Acambaro-Uruapan line of the merger system at Ajuno, a distance of 125 kilometers. The narrow-gauge Acambaro-Uruapan line is being shortened and widened. A rich portion of the State of Tamaulipas will be opened by the construction of a railroad south from Matamoros to the Gulf port of Tampico, and from Tampico an extension will be built through the State of Veracruz to the port of Veracruz. This line will connect with the present system at some point in the State of Hidalgo, thereby establishing a short route to Mexico City. Early this year the Durango government granted a concession for a railroad from Tepehuanes, the Mexican International terminus, into the Guanacevi mining district. The surveys have been completed and the district is being canvassed to determine probable freight. The concession carries the State's guarantee of 6 per cent interest on the money invested for a period of 25 years. It is stated that J. G. White & Co., of New York, will build the line.——According to late advices, the merger of the Dolores Mines Co. and the El Rayo Mines Co., both in Chihuahua, with the Mines Company of America, owning the Creston Colorado and La Dura mines in Sonora, is practically accomplished. The capital of the Mines company has been increased from $2,000,000, consisting of 2,000,000 shares of a par value of $1 each, to $9,000,000, consisting of 900,000 shares of a par value of $10 each. Of the new stock, 400,000 shares will be used in acquiring the same number of shares of Dolores stock, par value $5, and 249,914 shares will go to the holders of the 357,020 outstanding shares of El Rayo, par value $2. After all stock transfers are made the Mines company will have stock of a par value of $500,860 for use in obtaining funds for additional properties and improvements. Dividends paid by the three companies in 1909 totaled over $1,000,000. A few months ago the Mines company took over the properties of the La Dura Mining & Milling Co. in the Yaqui river region of Sonora, and these properties are now being operated under the Mines company management. The La Dura mines have been steady shippers of high-grade ore for many years.——The Elmore flotation process has been discarded by the Magistral-Ameca Copper Co., of Los Angeles, operating in the Ameca district of Jalisco. It proved satisfactory only in treatment of absolutely clean sulphide ores. The Magistral-Ameca was the first concern in Mexico to give the Elmore process a trial in the treatment of copper ores, and much interest was manifested in the results. Jigs, also, have been discarded by the Magistral-Ameca, and the treatment now consists of concentration on Wilfleys, tube-mill regrinding of middling and tailing, and slime-table treatment of the slime. This method having proved satisfactory, the plant is to be enlarged to treat 150 tons daily. Screen troubles, resulting from an excessive amount of sulphuric acid, have curtailed production recently.——The Almoloya Mining Co., of Mexico City, operating near the Magistral in the Ameca district, has paid its first dividend, 2 per cent on the capital of $20,000. A small plant is producing from two to three tons of concentrate daily. It will be enlarged during the coming year. ——The ambitious plans of the Mayo River Power & Land Co., of Denver, are again attracting attention, due to the announcement that funds for the projected power plant on the Mayo river in Sonora have been secured. A concession for hydro-electric development on the Mayo was obtained last year, and if a plant be built, power will be transmitted to Sonora and Chihuahua mining camps. The company plans are not confined to the Mayo river, but include hydro-electric installation on the Humaya river, in Sinaloa, and on the Santiago river, in Jalisco, or Tepic, with long transmission lines to many sections of the west coast territory. There is promise of great development along the west coast of Mexico during the next several years, and with the opportunities that exist for hydro-electric installations, cheap power should prove an important feature of this development. Engineers in the employ of the Denver company have measured the flow of all principal west coast rivers at the end of the last dry season.——An 89-mile transmission line, from Guanajuato to San Luis Potosi, has been completed by the Central Mexico Light & Power Co., a subsidiary of the Guanajuato Power & Electric Co. The distance from Guanajuato to the generating plant, in the State of Michoacan, makes the total transmission nearly 200 miles. The San Luis Potosi electric plant and distributing system were purchased some months ago for $700,000. The new line is delivering power to the Providencia San Juan de la Luz mines in the San Felipe district of Guanajuato, and later it is expected to deliver power to the San Pedro district of San Luis Potosi.——A concession was recently granted for a transmission line from the Copper Queen smelter at Douglas, Ariz., to the El Tigre district of Sonora, and it is expected to have the line completed before the middle of 1911. Power will be furnished the Lucky Tiger and other properties.

The September reports of the El Oro Mining & Railway

Co. and the Mexico Mines of El Oro, both controlled by the Exploration Co., Ltd., of London, show profits, respectively, of $92,580 and $82,190. The ore milled by the El Oro Mining & Railway amounted to 30,012 tons, and produced $199,140. The month's profit from the railway was $4000. The ore crushed in the 40-stamp mill of the Mexico Mines totaled 11,710 tons, producing $129,160. The annual meetings of these two companies were held recently in London, and reports for the year ending June 30 last were submitted. On that date the reserves of the El Oro Mining & Railway amounted to 441,639 tons, or approximately 15 months' supply at the present rate of milling. The total production for the year was $2,562,705, the total profits £227,192, and the dividend distribution £172,125, or 15 per cent. The total revenue of the Mexico Mines was $1,392,336, the profits totaling £154,990, and the dividend payments £126,000. The ore reserves at the end of the year amounted to 283,735 tons.——The successful development of the Juan Casiano field in the State of Veracruz by the Huasteca Petroleum Co. is proving of benefit to the Waters-Pierce Oil Co. in its war with the Pearson-Aguila interests, as a contract for the delivery of 2,500,000 barrels of oil to the Waters-Pierce refinery at Tampico has been made. It is stated that the Huasteca company will receive 92½ cents gold per barrel, or a total of $2,312,500, and that an advance payment of $250,000 has been made. The contract means that the Waters-Pierce will be able to greatly curtail imports. The Huasteca company has let a contract for a concrete storage reservoir of 500,000 barrels capacity, and later, if the production increases, a second concrete reservoir, possibly of greater capacity, will be built.

Control of the Hidalgo Mining Co., of the Parral district of Chihuahua, and the Parral & Durango railroad has been acquired by men principally interested in the Alvarado Consolidated Mines Co. and the Palmilla Milling Co. The deal was made by A. J. McQuatters, and is stated to involve $1,500,000. James I. Long, who has been in general charge of the two enterprises, confirms the sale of control. The deal means extensive work at the Hidalgo properties and may result in the extension of the Parral & Durango railroad.——The remodeled and enlarged smelter of the Rio Tinto Copper Co., in the Terrazas camp of Chihuahua, is now ready to handle up to 600 tons daily. Converters have been installed, and blister copper will be shipped.——The San Carlos Gold Mines, Ltd., the English concern owning the Mezquital and San Carlos groups and a 50-stamp mill and cyanide plant in the Mezquital del Oro district of Zacatecas, is averaging two bars of gold and gold-silver-copper bullion weekly. The bars are shipped to the Bank of London & Mexico at Guadalajara, and range in value from ₱6000 to ₱7000. English interests have owned these mines for a number of years, and several reorganizations have taken place. For a time substantial dividends were paid.

LOS ANGELES, CALIFORNIA

Gold Road Mine.—San Antonio Copper.—Meeting of Oil men.

The Gold Road mine, operated by the Gold Road Mining & Exploration Co., situated 24 miles northwest of Kingman, Mohave county, Arizona, and the same distance northeast of Needles, is preparing to increase its capacity to 300 tons per day. Recently two Chilean mills were installed, but they are not yet taking ore, as the shafting was broken when power was turned on. Repairs are being rushed. In the meantime the mill, of 40 stamps, two 5 by 22-ft. tube-mills and a cyanide annex, is treating 200 tons per day. The mine is developed by an 835-ft. shaft, from which 2000 ft. of stoping ground has been opened. Over 7000 ft. of drifts are open on the various levels. The ore averages about $9 per ton in gold with a small amount of silver.——The shaft of the Johnnie Mining & Milling Co., fourteen miles from Amargosa, Nevada, is down 930 ft., and preparations are being made to continue to the 1000-ft. level. A cross-cut is being driven on the 900-ft. level which is expected to reach the orebody in a few days. The ore now going to the mill averages above $10 per ton in gold. Plans for the next year include the installation of mining and milling equipment that will bring the capacity up to 150 or 200 tons per day. The mine is now developed to the point where this capacity is possible, but the equipment permits the handling of only 50 tons per day.——The San Antonio Copper Co., situated in the southeast corner of the Ures district, Sonora, Mexico, at the terminus of the Rio Yaqui & Pacific railroad, has completed surveys for a 4400-ft. adit to tap the vein 1200 ft. below the apex. The adit will be double-tracked and the portal will be about 2½ miles from the smelter site. The property is developed almost entirely by adits, of which there are 19, the longest being 1200 ft. About 30,000 ft. of work has been done. H. L. Miller, of Los Angeles, and associates, operating the Libertad and other claims to the south of the San Antonio property, are developing with a force of 20 men. Here nine adits, varying from 100 to 400 ft. in length, have been driven. The San Antonio vein is in quartz-porphyry, standing almost vertically and striking north-south; the Libertad vein is just beyond the contact, in slate, and strikes northeast-southwest. Although there are many prospectors in this district, the above operations are the only ones of magnitude.——The following call has been set out to the oil men of California: "In order to arrive at the best method to pursue in an effort to induce the Government to take immediate remedial measures in behalf of those operating in good faith upon Government land, whose interests have been affected for the worse by late interpretations of the laws governing mining claims, it has been determined to call together all those interested directly or indirectly in the matter; and all those to whom this is addressed are hereby earnestly urged to attend a meeting to be held at Bakersfield on Saturday, November 12, 1910, at which time and place it is hoped a plan will be suggested and approved whereby the rights of the said operators may be secured in accordance with the implied promise of the Government, and the general understanding of the laws in the light of rulings and decisions obtaining up to a recent date." The meeting will be held under the auspices of the California Oil Men's Association, Western Producers' Association, Kern County Board of Trade, and Coalinga Chamber of Commerce.

NEW YORK

Prosperity in Crops.—Silver Higher.—Copper Situation.—1000 Stamps for Alaska.

In New York attention is concentrated on politics and in Wall Street it is 'Anything to beat Roosevelt.' Aside from this distraction, market conditions are improved. Crop returns and crop financing were alike elements of uncertainty. Eight billions in corn, wheat, cotton, and other products added to the country's wealth, and the moving of such an enormous tonnage without undue financial strain, form a foundation for broad operations, and as soon as the decisions of the Supreme Court point the way in which certain projects must be carried out, it is expected some large enterprises will be put together as new leaders for the market. Silver has maintained an average price throughout October of 55 $^{9}/_{16}$c. per ounce. The high mark for the year was 56⅞c., reached in October. Silver producers are particularly encouraged by demands of the Orient. The stimulus to the silver mining industry which will follow the metal market improvement will be most apparent in those districts having large low-grade orebodies. In copper, the improved conditions are considered a triumph for the advocates of curtailment. Consumption of copper continues to climb to record-breaking proportions and that the metal goes into use is shown by a marked decline in the foreign visible supply. The metal market is announced as sold out for 1910 deliveries, while one of the largest of the selling agencies announces heavy sales made for January delivery, which is quoted at 13c. with higher prices in prospect. So long as the present rate of consumption is maintained the big producers will exercise caution in advancing prices, relying rather upon the volume of business than upon profit per pound.

One of the remarkable financial movements of recent

years is the concentration of copper interests and the close relations of the more powerful factors. It has been thought that so far as production is concerned an agreement had been reached covering not only curtailment for market purposes, but also the development of new properties, a sort of amicable division of territory, leaving open smelting profits and metal brokers' commissions. There is recent evidence that competition here has also been eliminated. Not long ago the Miami made a contract with the Cole-Ryan interests to send its ores to the Greene Cananea smelter. This was supposed to merely emphasize the alliance of the Lewisohns with the Cole-Ryan, Amalgamated, and Standard Oil crowd. Now the Lewisohns have made another smelting contract, this time with the Guggenheims, who hereafter will handle the ores of the Tennessee Copper and will also have the selling of the 14,000,000 lb. of copper produced by the Tennessee. Inasmuch as this means direct loss to the United Metals Selling Co. in commissions, and as control of Tennessee rests with the estate of Leonard Lewisohn, the only conclusion to be drawn is that copper producers, smelters, refiners, and selling agents have come much closer together than the public thought.

The rumored dividend of the Granby failed to materialize. The company has, however, taken steps in the line of the campaign promised, in the purchase of control of the Hidden Creek Mining Co., which is said to own the largest copper deposit in British Columbia. These properties are at Goose Bay, on Observatory Inlet, near the Alaskan boundary. Calaveras Copper, which has been having a somewhat spectacular career on the Boston curb fell from $7 to $1.87½ in one day. It was said the slump was owing to a forced sale of stock held as collateral.

The 200-stamp mill of the California Nevada Copper Co., on the Ebner property near Juneau, Alaska, is going up rapidly. The stamps in this mill weigh 1500 lb. each and will drop 105 times per minute. The ore of the Ebner is said to be free milling and to run about $3.50 per ton. The equipment now under construction is the first unit, and plans contemplate the installation of 1000 stamps as quickly as possible.

A reorganization is to be effected of the Alvarado Consolidated Mines Co. and the Palmilla Milling Co., originally organized to exploit the old Palmilla mine at Parral, in Chihuahua, Mexico. The Boston people concerned have taken the property over in fee simple. The present plan contemplates the formation of a company to be known as the Alvarado Mining & Milling Co. The old stock in the two companies will be exchanged on a basis of two shares for one, that is, two shares of Alvarado Consolidated or two shares of Palmilla Mining, or one share of each, for one share in the new company. After the exchanges are completed it will leave 200,000 shares of new stock in the treasury to be used for the purchase of other properties. A new cyanide mill on the property is about completed and will go into operation as soon as the aerial tramway from mine to mill is finished.

BUTTE, MONTANA

North Butte and Tuolumne Negotiations Dropped.—Amazon-Montana.—Parrot.—Ohio-Keating.—Raven.

The negotiations between the North Butte and Tuolumne companies for a settlement of their differences have ceased, according to latest reports. It is impossible to secure official information as to the nature of the offer made by the North Butte company, but it is reported that the Tuolumne would not sell upon a basis of less than $8 a share, while the North Butte people would pay no more than $6 a share. It is generally understood that W. A. Clark has not taken up any of the bonds to which he was entitled in proportion to his holdings of Butte & Superior stock. There is an unofficial statement that, of the $1,000,000 bond issue, the stockholders took $250,000, an Eastern bonding company $500,000, and the remainder will be taken by Duluth people. There is a belief that some deal as to finances is still pending with W. A. Clark, as it is said a shipment of 1000 tons of ore is being made to his concentrator. Walter Doe, who is in charge of the Abe Lincoln mine in the Moose Lake mining district, west of Anaconda, has gone East to consult with stockholders in reference to improvements and development. He recommends a plant for the treatment of the ore.——According to reports from the Amazon-Montana Development Co. at Amazon, 35 miles east of Butte, some fine ore has been discovered. It is stated that the crosscut has intersected a vein 8 ft. wide at a depth of 250 ft. In the bottom of the winze on the main ore-shoot, at a depth of 40 ft., ore was found, an average sample of which assayed 10.2 oz. silver, 26.6% lead, 2% copper, and $2.50 gold to the ton, a total value of about $32 to the ton.—— It seems a good thing for Parrot stockholders that the property was purchased by the Anaconda company, otherwise it is uncertain when they would receive a dividend. In 1900 the Parrot paid a dividend of $6. In 1901 it paid $4.50, and the next year 50 cents. The following year it was passed. In 1904, $1 was paid, and in 1905, $2. In 1906 it was $1.25 and in 1907, 75 cents. The two following years the dividend was passed. Since the property was sold to the Anaconda company the Parrot company is again in a position to pay dividends from the $180,000 a year it is getting in dividends from the 90,000 shares of Anaconda company stock which it received from the sale. The first dividend since 1907 was 15 cents on September 7 of this year, which has been followed by another of 15 cents a few days ago. There is a belief that the action brought by the minority holders of Parrot stock will never come to a hearing, but that the petition for the appointment of appraisers to value the property will be dismissed by the men bringing the action, with the understanding that the Parrot company be dissolved and that the 90,000 shares of Anaconda stock held by the company be divided among the stockholders pro rata.——A special meeting of the Ohio-Keating Gold Mining Co. has been called for December 3 by directors to place before the stockholders a proposition to raise money. It is proposed to increase the capital stock from $500,000 to $1,000,000, and to offer a part of the new stock to stockholders, and the unsubscribed portion to the public; to authorize a mortgage-bond to care for the present indebtedness and for future requirements, and also to consider the advisability of consolidating with other companies, or of selling all of the company's assets. The property of the Ohio-Keating is at Radersburg, in Broadwater county, and several months ago in New York there was a merger under consideration with a concern in California, but it seems that scheme fell through, and now another way is to be taken to raise money. According to reports from company officers a short time ago, an excellent showing was being made.——There is a feeling of satisfaction in Butte over the announcement that the Raven company has made arrangements with the Amalgamated Copper Co. which will enable it to work the Snoozer claim, adjoining the Amalgamated properties. The Raven owns $^6/_7$ and the Anaconda company $^1/_7$ of the Snoozer claim. Development proceeds in the Raven and the agreement entered into with the Amalgamated gives promise of great things for the Raven people.——The quarterly report recently issued by the North Butte Mining Co. shows that extensive development has been done since the last report and that some valuable orebodies have been opened. Altogether the property is in a much better condition than for a long time. The Speculator shaft has been sunk an additional 120 ft. and the skip, chute, and station at the 2400-ft. level have been completed. Sinking is now going on to reach a depth of 2800 feet.

The Tuolumne Copper Mining Co. is shipping daily to the Anaconda smelter 230 tons of ore which runs 11% copper. While there is a force of men mining and hoisting ore, there is also a large force engaged in development work, and the company is proceeding along the lines that there is no question as to the future of the property, to the value of its ore, or to it remaining in the possession of the present owners. Mr. Harrington, the secretary, says that the company is earning good money on the present market value of copper, while Mr. Sheehan, the superintendent, is authority for the statement that the supply of ore in the new strike is practically unlimited.

General Mining News

ARIZONA

GILA COUNTY

(Special Correspondence.)—D. C. Jackling, manager of the Ray Consolidated Copper Co., and a party of friends arrived in Globe, November 3, for the purpose of examining the property of the Inspiration Copper Co. and making a trip through the Globe-Miami district. Mr. Jackling and some of his associates are supposed to have become financially interested in the Inspiration mine.——The Miami Copper Co. is employing 600 men, of whom only 75 are underground. The remainder of the force is engaged in constructing and equipping the concentrator and auxiliary buildings. The company has provided foundations for three additional units at the concentrator site, but the equipment for increasing the capacity of the mill from 2000 to 3000 tons will not be added until conditions warrant. It is estimated by the management that one year from now the mine will be producing 2000 tons of ore every 24 hours with a force of 350 men.——The Arizona-Colorado Copper Co. has a small force on development on the second and eighth levels. Two machine-drills are in operation, one on a stope in the eighth level, where a vein 8 ft. wide is being worked, and the second on the 200-ft. level, where a cross-cut is being driven south from the shaft to open a vein 30 ft. from the station. This cross-cut is now in 15 ft. From the eighth level stope about 15 tons of ore averaging 4% copper is being extracted daily.——All efforts of the Arizona-Michigan Mining Co. to find ore are now confined to sinking a winze on the Old Dominion fault below the fifth level.——The Superior & Boston Copper Co. is employing 75 men. The underground work consists in driving two drifts on the eighth level and of sinking the McGaw shaft. This shaft is 940 ft. deep.

Miami, Arizona, November 5.

YAVAPAI COUNTY

(Special Correspondence.)—The Haynes Copper Co. at Jerome is developing. The work at present is in oxidized ore containing gold and copper. Three shifts, totaling 25 men, are employed. Electric pumps handle the water and are giving satisfaction. T. E. Campbell is superintendent and general manager and William Jansen is foreman.——The Arkansas & Arizona property north from Jerome has resumed after a shut-down of several months. The present work consists of sinking and putting stations in the main shaft. Electric pumps have been installed. Charles Lynch is superintendent.——The Jerome-Verde Co., whose property lies just east of the town of Jerome, is sinking the main shaft, which is down over 500 ft. When the 700-ft. point is reached, driving will begin. Twenty men are employed.

Prescott, November 4.

CALIFORNIA

CALAVERAS COUNTY

The North Star mine near Angels has been recently equipped with a 20-stamp mill. The Angels mine is in operation, and the Utica is expected to resume operations soon.——The Gold Cliff mine, at Angels, has been equipped with a new 20-stamp mill which is run by electricity.——The Schmedake mine, west of Angels, has been bonded to an English company.——The Tulloch mine, south of Angels, is in operation.——The Silver valley reservoir is about finished and will soon be able to furnish a steady supply of water to mines near Angels.

MODOC COUNTY

(Special Correspondence.)—The Ft. Bidwell Con. Co. is installing a 5-stamp mill at its property in the Hoag district. It is expected to have this plant in operation early in December. The mill will be built at the Mountain View, where milling ore has been developed. An aerial tram line is being constructed from the Sugar Pine claim to the millsite, and ore from this property will also be treated. In the latter property rich ore was recently reported. Algernon Del Mar is manager.——The Big Four company has placed an order for a 5-stamp plant, and expects to commence ore treatment before the end of December.——It is expected to have the recently completed custom mill in operation as soon as the fall rains supply sufficient water.——Vigorous work is under way at a number of properties with promising indications.——At the Hess mine, near Adin, the company is constructing a bunkhouse and preparing to increase its force to 30 men.——Some promising ore is being opened in the Dixie Queen.——Prospecting in the hills around Adin is unusually active, the search extending over a wide area.

Alturas, November 2.

NEVADA COUNTY

The channel of the Oak Flat mine near Columbia hill has been cut in a raise from the drainage adit driven through the bedrock beneath the channel. Where the raise reached the channel it is evident that it is on the rim, consequently the adit will be extended and the bottom of the channel sought. Arrangements will be made to wash the gravel as soon as it is available.——A find of rich ore in the Cassidy mine, adjoining the Enterprise at Grass Valley, is reported. The vein is 2 ft. wide. As soon as development warrants it, a mill will be built.

PLACER COUNTY

A drift from the bottom of the shaft of the Standard mine in Sailor ravine, east of Forks House, is cutting stringers of quartz which carry rich arsenical sulphide. It is thought the pay-shoot is near.

SIERRA COUNTY

The York custom mill, near Downieville, is crushing ore from the Mexican mine, on the South Fork of Feather river.——S. W. Van Sycle is working the Keystone mine near Sierra City, under option. An electric-power line is being built to the mine.——At the Cremone mine it is said the vein is a dike 40 ft. wide carrying gold from wall to wall.——George Jones has located a dike 100 ft. wide at the forks of Wolf creek that carries gold and copper.

COLORADO

CLEAR CREEK COUNTY

What has been done at the new camp of Beshears directs attention to a comparatively unprospected belt extending from Boulder county through Gilpin and Clear Creek into Summit county. There is a general opinion that more thorough prospecting will lead to the discovery of valuable orebodies, not only at Beshears, but at other points in the same zone. Beshears is at an altitude of 11,000 feet.

LAS ANIMAS COUNTY

At least 35 men were killed by an explosion in mine No. 3 of the Victor American Fuel Co. at Delagua on Tuesday last. The bodies of 35 men were found in the north entry where the explosion occurred. Four men were rescued, though Willis Evans, a young engineer of the Colorado Fuel & Iron Co. lost his life in the rescue of four miners. He was an assistant on the C. F. & I. Co.'s rescue car. The rescue car of the United States Bureau of Mines in charge of J. C. Roberts arrived at the mine Wednesday morning, and he and his men at once began work with the company's men.

TELLER COUNTY

Following is a statement of the tonnage and value of ore from Cripple Creek district treated during October:

	Tons.	Average Value.	Gross Value.
Golden Cycle	25,660	$20.00	$ 513,200
U. S. R. R.	12,800	22.00	281,600
Portland (Colo. City plant)	10,000	20.00	200,000
Portland (Battle Mt. plant)	8,000	3.50	28,000
Stratton's Independence, est.	8,000	3.50	28,000
Smelters	4,315	65.00	380,475
Total	68,775		$1,432,075

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—The Tiger-Poorman Mining Co., whose mine is at Burke, in the Coeur d'Alene district, which has disbursed more than $3,000,000 in dividends, will go out of existence and the property, idle since 1908, will be abandoned. The petition for dissolution was signed by Bruce Clendenning, president, and W. J. Hall, secretary. The expense of handling water was very large and at the 1900-ft. level the task proved too great.——The Northwestern Sampling & Milling Co. will also go out of existence on November 25. The corporation operated for years in conjunction with the Tiger-Poorman company.——The Hecla Mining Co. at Burke paid a monthly dividend of 2c. a share,

Helmet Used by U. S. Bureau of Mines in Rescue Work.

or $20,000, for October, bringing the dividends paid to date to a total of $1,070,000 on a capital of $250,000.

Spokane, November 5.

KANSAS

CHEROKEE COUNTY

(Special Correspondence.)—At Galena preparations are being made for still greater activity. Chief among important transactions is the purchase of the old Southside tract which has produced thousands of dollars worth of ore. Franklin Playter has plans for putting the tract on its old basis. Most of the old machinery has been discarded as unfit for further use, and modern machinery will replace it. A pump with a capacity of 1500 gal. per minute has replaced the old pump used in the Nevada shaft. This new pump will drain most of the Southside tract and make it possible to employ a large force at once. New prospects will be opened as well as the old shafts. The upper runs will be developed while sinking to the rich lower levels which are untouched.——The Nymo plant, which was damaged by a recent storm, has been repaired and is working double shift. Mining has been done at 100 ft. and an ore face 30 ft. high has been carried. Two shafts have entered ore at 135 ft. which assays 6%. A third shaft is used for pumping.——The large Eureka mill, which is comparatively new and was built by A. O. Ihlseng and later sold to Robert Ping, is running. The mine is operating at 300 ft., the deepest level worked in the entire district. There is a 3-compartment shaft, sunk on the dividing line between the Ping and Robertson leases, and ore is taken from both lands. Drifts were first started at 275 ft., but were found to be above the main deposit.——A new drill-hole find has been made on the Clermont land south of Shoal creek which is similar in richness and depth to others on the same land. This company is constantly prospecting and developing its immense holdings and has enough ore in sight to insure steady operation for many years. The last find was between 158 and 173 ft. in black flint. Another recent drill-hole 500 ft. north of the mill shaft showed practically the same formation as well as a deeper deposit in the mill shaft.——Another good prospect has been opened on the Porter tract, across Shoal creek, where 12 ft. of rich ore and 23 ft. of fair mineral were cut in a shaft sunk on a drill-hole. The best ore is estimated to run 8 to 10%. The shaft is down 105 ft. and will be sunk 12 ft. deeper. A drill-hole east of this shaft shows still better ore.——The Kramer mill has just been removed from Badger to the Herald lease in Cave Springs, owned by H. L. Kramer. This has been an important mine, developing one of the deepest deposits in the district. But owing to the grade of zinc and the depth of the run, careful milling was required to make ends meet. The old mill was dismantled and the new plant will be tried with more adequate equipment.

Galena, November 4.

MISSOURI

NEWTON COUNTY

(Special Correspondence.)—The old Seneca camp is being developed by local and outside capital as well. Chief among the producing mines are those on the Becker land where prospecting is proceeding on a lease recently acquired; also on the older tracts. The ore being milled is found on a lower level than previously mined. Other producing mines are east of town on the Gallemore land, where galena in abundance is taken from a depth of 15 to 30 ft. There are also silicate and zincblende on the land at deeper levels, but the company will first develop the shallow runs.——Potter and Buskett, who have been developing land west of Diamond, have leased 10 acres to Ivy and Daniels. The ground has been well opened and the shaft furnishes a good supply of ore, which is cleaned on hand jigs. Two shipments have been made. There is some difficulty in the proper separation of the ores, as calamine, galena, and zincblende are all intermixed. But with a new milling plant this will be more easily accomplished. The new lessees have contracted to build a plant during the coming year.——Another new prospect is being developed by W. T. Matters and associates of Neosho, at Henderson, a small mining camp west of Spurgeon. Already a fair amount of lead has been found while sinking. The drill-hole showed good ore from 26 to 36 ft., and the shaft was sunk 3 ft. away. A small prospecting outfit has been put in, including hoist, boiler, and steam-pump. The new prospect is in the midst of old shallow holes which were good producers of ore in an earlier day.——With coal again on the market many mines have resumed operations which were handicapped for lack of it. The old De Masters mine south of Spring City is again operating after being dramed, and the Milne silicate mine, just across the road from it, has also resumed operations. Formerly a heavy output of calamine and blende came from here.

Seneca, November 5.

MONTANA

SILVER BOW COUNTY

(Special Correspondence.)—The October copper production by the Butte mines aggregated 22,913,781 lb., against 22,990,050 in September. The total ore tonnage and copper production for the month are given on the following page.

	Tons ore mined daily.	Lb. copper per ton of ore.	Lb. copper prod. in month.
Boston & Montana..	3,000	72	6,696,000
Anaconda	4,000	62	7,688,000
Washoe	400	61	756,400
Parrot	125	63	241,125
Trenton	423	62	813,006
North Butte	1,000	62	1,922,000
Butte-Coalition	1,200	66	2,455,200
Tuolumne	200	70	434,000
East Butte	250	95	736,250
Original	600	63	1,171,800
Total			22,913,781

B. B. Thayer, president of the Anaconda Copper Mining Co., has completed his inspection of the mines in the district. It is stated that after allowing for cost of production, freight, selling charges, and a liberal depreciation, copper is being put down in New York by the Anaconda company at about 10c. per lb. Butte-Coalition operates at the lowest cost of any mine in the district. Mr. Thayer says that mining is to be resumed in the West Stewart, one of the old Clark properties. A spur from the Butte, Anaconda & Pacific railway to the mine has been completed to allow shipment of ore to the Washoe smelter. It is intended to work the Little Mina, of the Parrot company, through the West Stewart shaft.——The Gagnon is hoisting 500 tons a day. The new shaft which was started on the Gagnon ground some months ago is down 1000 ft.——Sinking is proceeding in the St. Lawrence mine. The shaft will be sunk to the 2800-ft. level of the High Ore, with which a connection will be made. All the Anaconda hill mines will be connected with the High Ore for drainage purposes. The 2800-ft. level of the High Ore is the deepest working level in the district, although the Diamond shaft is about 3000 ft. deep.

Butte, November 5.

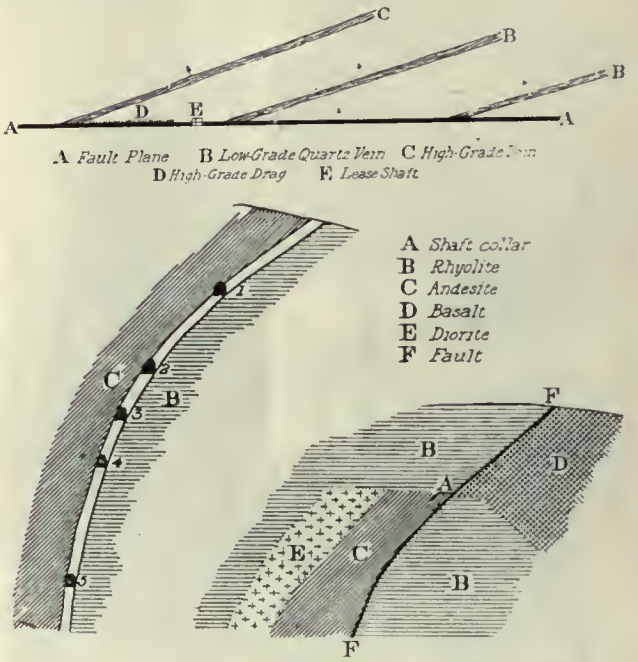
NEVADA

HUMBOLDT COUNTY

(Special Correspondence.)—The Safford lease on the Mammoth claim of the Sheba has opened a large vein at a depth of 10 ft. The vein carries gold, silver, and lead, the two latter predominating. There are several streaks of high-grade ore, assaying up to $400 per ton.——It is reported that 12 ft. of milling ore has been cut by the Charleston Hill Gold Mining Syndicate, at National.——Walker Bros. report rich ore on their Jewsharp Bell claim.——A vein of quartz and talc has been found at the Lady Bud while doing assessment work.——The National Defiance lease shaft is 100 ft. deep, and a cross-cut is being run. A hoist has arrived.——The Butler, Hyde & Prout lease continues in excellent ore. It appears to be the northern continuation of the Charleston vein.——The Crawford Leasing Co., of Salt Lake, has secured the Kekler lease on the Mayflower. This adjoins the original lease of the Crawford.——The Edmonds lease on the Mayflower continues in rich ore. This lease made the second important find of high-grade ore in National——Barret Springs, 8 miles west of Winnemucca, is attracting considerable attention owing to promising discoveries on numerous claims. At the Nineteen Ten a shaft has been sunk 90 ft. with 3 ft. of ore in the bottom. Several streaks of shipping ore were encountered while sinking. Seven sets of lessees are at work on the property. A carload of ore was recently sent out by the company.——The Laurel shaft is down 146 ft. and sinking. A gasoline hoist is used.——A half interest in Remolia No. 1 claim has been secured by G. W. Hartley of New York and T. Defenbaugh of National.

Winnemucca, November 4.

(Special Correspondence.)—The property of the National Mines Co. passed to the control of John E. Pelton and associates September 15, 1909. They had previously purchased the group of four claims of J. L. Workman and Lee Davis, who located them in June, 1907. The unexpired lease of Stall Bros. on a block 300 by 300 ft. was surrendered to the present owners a few months ago, for $250,000. It is reported that this block of ground, after the lease had been relinquished, produced this amount in gold in 28 days. Development on the property aggregates 9000 ft. in drifts, raises, and winzes. Adit No. 4 on the vein gives a depth of 580 ft. at the face. No. 5 adit, starting from the bed of the gulch, has advanced 1100 ft., and when driven beneath the workings of Stali Bros. will be over 900 ft. below the surface. The principal vein, known as the Charleston Hill, is said to have been proved for 2500 ft. Some ore running $20 to $100 per lb. has been shipped by express; other ore is said to sample $1500 per ton; what is designated as mill ore runs $30 per ton. It is estimated there is 6000 tons of mill ore on the dump. A Lane mill, crushing 20 tons per day, has been in operation for some time. The gold occurs free in quartz, talc, and eruptive material. There is a dike of porphyry striking north-south through the district, within which the several parallel veins of ore occur. The accompanying sketch shows the geology of Charleston Hill and of the veins as determined by H. C. Cutler in a preliminary survey of the district.



Geological Sections, National, Nevada.

The Auto Hill Extension, owned by J. L. Workman, and leased to Phil Blume, of Winnemucca, is opened by a 200-ft. shaft, from the bottom of which 200 ft. of driving has been done on the Auto Hill vein. The ore is said to assay $12 to $100 per ton. This vein is parallel to the Charleston Hill.——The Radiator, under lease and bond to O'Connell and associates, of Seattle, is opened by a 700-ft. cross-cut to the vein. Sinking and raising are in progress.——The Mayflower, covering another vein, is owned by E. Rhinehardt and W. Critchfield, of Winnemucca, and is leased to R. Edmunds, who has reached the vein by a 400-ft. cross-cut. He intends raising 230 ft. on the vein to the surface. A gasoline hoist is to be installed.——Several sets of lessees are developing on the north end of the National veins, including M. E. Atkinson and Hyde & Prout, the latter having a 200-ft. cross-cut and 200 ft. of driving on the vein.——The Indian Valley lease on a block of National ground, is controlled by E. A. Montgomery, who has sub-leased it to Gordon Campbell and Mr. McDonald. They have found ore and are sinking.——The Shilo group, situated on the south end of the zone, is being developed by George H. Snowden and associates, of Seattle.——J. L. Workman is cross-cutting and driving on the Auto Hill and White Rocks groups. Two veins were intersected by a 300-ft. cross-cut.——The population of National is about 500. It is claimed there are 250 men working for wages, 80 to 100 of this number being employed by the

National Mines Co. The distance to camp from Winnemucca is 80 miles, the automobile fare being $20 each way.

National, November 5.

LANDER COUNTY

(Special Correspondence.)—The reconstruction of the mill of the Austin-Manhattan Co. has been completed and four electric motors installed. Dry concentration will be employed. The management reports that favorable rates have been secured for the treatment of Austin concentrates. For an emergency fuel supply 500 tons of coal is being placed in bins.——Sinking in the Jack Pot shaft has reached the 300-ft. level and will be continued to the 400-ft. point. From the 300-ft. level a cross-cut has been started.——The retimbering of the Ophir shaft is finished below the 200-ft. level and will continue until the Union vein is reached. The Union portion of the group will be opened through this shaft.——A chute is being built at the station where the Lander adit intersects the Frost shaft, to handle ore from the Independence vein. The Frost shaft is being deepened. Much of the ore for the new mill will come from this point. The Independence will be worked through a cross-cut connecting with the Frost shaft at 570-ft. point. ——The Maricopa Mines Co. has put in a compressor at the True Blue, in New York canyon. A 100-ton mill and power plant have been ordered. The True Blue adit to open the Patriot will be driven with three shifts.

Austin, November 3.

(Special Correspondence.)—Battle Mountain, situated on the Southern Pacific, in the northern part of Lander county, is the supply centre for several mining camps to the southeast and southwest, and is the station from which the Nevada Central railroad extends up Reese river 92 miles to Austin. The Shoshone mountain range, between Reese valley on the west and Crescent valley on the east, is a mineralized region, noted in earlier years for the great production of gold and silver of the Dean mine, situated on the west slope, and of the Tenabo and Cortez mines on the east side. A camp of present interest is Kimberly, 18 miles southeast of Battle Mountain, up toward the crest of the Shoshone range. The camp of Kimberly, where there is a good-sized hotel, is at the confluence of two deep arroyos, and the group of 22 claims of the Kimberly Consolidated Mines Co. lies mainly between the two arroyos, which diverge widely as they are followed up toward the summit of the range. On the ridge between the two gulches is a mineralized zone, striking north and south, and approximately 400 ft. in width, the material of which is andesite, quartzite, and porphyry. Within the zone referred to are a number of parallel veins, separated from each other by quartzite and porphyry. On the north end of the group a surface cut on one vein showed it to have a width of 78 ft. between an east wall of quartzite and a west wall of porphyry. The cross-cutting and driving on this vein of quartz disclosed free gold throughout the most of it, with some remarkable specimens. Farther south, on the same zone, from a number of open-cuts and adits, quartz was taken that panned free gold. On the south slope facing the main Kimberly gulch, and near the centre of the group, are two shafts, 70 and 88 ft. deep, respectively, over one of which is a head-frame, and here a gasoline hoist is to be placed. The plan is to sink 400 to 500 ft. at each shaft, and drive cross-cuts to the veins. Besides what appears to be a north-south contact running through the group, there are transverse strata and dikes of quartzite and dacite which enclose the central part of the group in a mineralized basin. The claims of the group were acquired and consolidated by M. C. Scully, general manager for the company. The foundation for a mill has been put in, but further work has been deferred until development is more advanced. S. E. Montgomery, of Battle Mountain, is engaged in ore-testing, sampling, and studying the geological features of the group.——The Pittsburg-Red Top Mines Co. of Los Angeles has 700 acres of patented mineral ground lying between the Kimberly group and the Dean holdings, on which considerable development has been done. In driving a 725-ft. cross-cut several veins were intersected, on one of which a 115-ft. raise was made in ore. This cross-cut gives 200 ft. of depth on the veins, and a lower adit will give 520 ft. of backs. The veins have a width of 4 to 6 ft., strike north and south in limestone and porphyry, dip west, and contain ore that carries free gold and telluride of gold in a quartz gangue. A shipment of selected ore assayed $450 per ton. There were six miners at work at the time of my visit, and this force was to be increased to fifteen. The work is in charge of J. O. Glover. W. J. Grindle of Los Angeles is manager. The latter states that the company contemplates erecting a concentrating and cyaniding mill.

Battle Mountain, October 26.

NYE COUNTY

(Special Correspondence.)—Portland, Ore., capitalists have bought a large block of stock in the Gold Chief Mining Co., owning a mine in the range northwest of Caliente, Nev. The company is erecting a mill at the Gold Chief mine which is expected to be in operation in December. A pipe-line is being laid from Yoachum's ranch between Caliente and Panaca. The ore is said to be similar to that at Mercur, Utah, but of higher grade; and it is claimed that there are 50,000 tons of ore developed above the 200-ft. level of the mine.——In a suit brought by the stockholders of the Great Western Mining Co. at Hornsilver, to prevent consummation of a lease and option to purchase given by officers of the company to A. J. Trumbo and associates of the new Bonnie Clare Mining Co., and recently tried at Goldfield, the plaintiffs were defeated. Pending the possible construction of a branch railway from Stonewall to Hornsilver, a distance of 17 miles, a 26-ton traction engine, hauling 6 wagons of 15 tons each, will transport ore from the Great Western to the railroad at Stonewall, whence it goes by rail to the new Bonnie Clare mill, which it is expected will be in operation by January 1, 1911.

Rhyolite, November 5.

(Special Correspondence.)—The Eclipse Development Co. has built a 40-ton mill on Tramp Cons. near Rhyolite and is ready for custom ore. It includes a Vezin sampler. It is reported that the Diamond lessees will put in a gasoline hoist. Shipments of fair-grade ore are being made from workings above the 300-ft. level and from the dump.——The Dreyer lease is sending small quantities of rich ore to the Eclipse mill. The vein is reported to be 3 ft. wide on the 50-ft level.——A new lease has been taken on the Gibraltar Mines Syndicate by local miners.——The old Lida district is showing activity. The Lida Queen has been leased by Goldfield people and work commenced. The vein is 20 ft. wide with fair gold content. The ore will go to the Pigeon Springs mill. Charles Patrick is manager.——Work has been resumed at the Storm Cloud and the adit is in 1200 ft. A large vein of ore running $10 in gold and silver has been cut.——At the Nevada a 15-hp. hoist has been installed and the shaft will be sunk to 300 ft., where cross-cuts will be driven. The ore assays $12 per ton.

Rhyolite, November 3.

STOREY COUNTY

Preparations are being made to stope ore in the 2400-ft. level of the Ophir mine, on the Comstock. This is the deepest mining, other than development, done on the lode in many years.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine Mining Co., developing in the eleventh level, has 8 ft. of high-grade ore. But 20 stamps were dropped the past week, crushing 554 tons, from which 3 tons of concentrate was produced. ——At the Deadwood mines the shaft has been sunk below the 500-ft. level, and a station is being cut. Mill construction is progressing and the tanks are being erected.—— The Gold Dust Mines Co. is establishing a camp at the mines.——In the Socorro mines a new orebody averaging $16 per ton has been opened by a cross-cut on the 500-ft. level. Eight hundred tons of ore was milled and the 3-

compartment shaft was sunk 14 ft. during the week.——Enterprise Mining Co. is making progress in retimbering the Perseverance shaft. In the Enterprise the second and third levels are advancing toward the Perseverance.——On the Treasure Mining & Reduction Co. property a force is at work in the mine, and ore is being delivered by wagon to the mill.

Mogollon, November 4.

OREGON

BAKER COUNTY

(Special Correspondence.)—It is reported that the old Highland mine near Baker City has $400,000 worth of ore in the bins and stopes, and is once more in successful operation.

Spokane, November 5.

LANE COUNTY

(Special Correspondence.)—The Blue Bird Mining Co., Blue River, with S. M. Carter as president and general manager, has its 50-ton plant in operation on free-milling gold ore. There is plenty of ore, timber, and water available. The plant is equipped with the Denver Quartz Mill & Crusher Co. machinery.

Blue River, November 4.

UTAH

WASATCH COUNTY

(Special Correspondence.)—Free & Taylor, of Salt Lake, who have the contract to drive the Snake Creek drainage adit 14,350 ft., have run 1800 ft. since June 1. It will terminate in Daly-Judge ground. The size is 6½ by 9 ft. The track has 30-lb. rails and 5 by 7 in. ties, below which is a concave waterway for drainage. They use an electrically driven air-compressor with Sullivan and Pneumatic Tool Co. drills. The formation thus far is blue limestone.

Park City, November 5.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—With the payment of $71,428 the Queen Mines, Inc., last week took up the bond on the Queen mine, of Sheep creek district. The total price paid was $175,000. M. P. Cannon, of Morrillan, Wis., and G. O. Linderman, of Osseo, Wis., president and secretary of the syndicate, visited the mine last week. There are 15 claims included in the deal. The equipment on the Queen comprises a 5 and 10-drill air compressor, 10-stamp mill, hoisting, and pumping plant. The Queen Mines, Inc., is a close corporation of Wisconsin business men. E. V. Buckley is manager.——The final payments on the Nugget mine were made recently, the price aggregating $40,000. In December the final payment on the Kootenay Belle, amounting to $90,000, will be made, and the property will pass to the Rodgers syndicate. Early in January the Mother Lode mine will pass into possession of John McMartin, of New York. Price, $175.000. Owners of the Kootenay Belle will build a stamp-mill for the Mother Lode mine. The owner, John McMartin, and his engineer, William Watson, left for San Francisco to make arrangements for a 50-ton plant. ——A shipment of mixed zinc ores from this district is to be made to Ottawa for a test. Eugene Haanel has made an inspection of the Nelson electro-thermal zinc smelter with a view to determining its adaptability to the tests on a commercial scale.

Nelson, November 4.

(Special Correspondence.)—It is stated that a site has been purchased for the erection of a steel plant within 6 miles of Vancouver, on tide-water. W. Owen, representing British capital, is interested and is negotiating for iron properties within 35 miles of the proposed plant.——Engineers are planning the development of 50,000 hp. on the Puntridge river. This venture is backed by the Canadian Colliers (Ltd.), of Comox, and the power will be used in and about the company's mines. The plant will cost $1,000,000.——Sixty miles north of Vancouver prospectors have located a vein on the seashore that is 400 ft. wide, assaying 2% copper and $1.10 gold and silver. Nearby a bed of gypsum 60 ft. wide has also been located and traced for a quarter of a mile.——In Kamloops district the Iron Mask property should soon be again producing. On the Laura Group, Big Four, Watch Hill, and Arnold properties much work was done the past season. The coal formation north of Kamloops on the Thompson is being explored by the Canadian Northern Coal & Coke Co. by means of diamond-drill.

Vancouver, November 4.

(Special Correspondence.)—The board of directors of the Le Roi No. 2, Ltd., operating the Josie group, declared a dividend of two shillings per share, payable November 8. The managing director of the Le Roi Mining Co. denies that the Great Northern has been negotiating for the mine, but states that there are others figuring on taking over the property. Last week 25 men were put to work underground. ——Work on the Blue Bird mine in the south belt is proceeding with satisfactory results and the orebody is still strong. A recent assay returned $81.90 per ton.

Rossland, November 3.

(Special Correspondence.)—Ore shipments from the Boundary district the past week were gratifying, the Granby, Jackpot, Mother Lode, and Rawhide mines showing an increase over the preceding week; in the case of the Granby the increase amounted to nearly 5000 tons for the week.——F. M. Sylvester, of Spokane, has arrived in Phoenix and will take the position of assistant manager for the Granby Consolidated company.

Phoenix, November 4.

(Special Correspondence.)—Mining at the Fife mines was suspended during the past week, pending the installation of more machinery. It is expected that this addition will be completed in three weeks.——It is proposed to sink to the No. 10 level of the Ymir mine in the spring, according to P. F. Jaynes. The No. 10 adit has been driven on the vein for 2160 ft. and is the lowest opening on the property. There is enough ore in the vein, although low grade, to make the Ymir mines profitable under existing shipping and smelting conditions.——The shipments from the Slocan-Kootenay district for the week ended October 22 were 5252 tons.

Nelson, November 4.

(Special Correspondence.)—Eighty per cent of the capital stock of the Hidden Creek Mining Co., owning the largest copper deposit in northern British Columbia, was acquired for $400,000 by the Granby company in Spokane, October 25. M. K. Rodgers, manager of the property, formerly manager for Marcus Daly at the Nickel Plate mine at Hedley, B. C., and who owns the remaining 20 per cent of the stock, refused to sell his interest at any price. Jay P. Graves, of Spokane, vice-president and general manager for the Granby company, announced that a matting plant will be erected as soon as sufficient tonnage is developed. It is the intention to make a low-grade matte and to ship it to Grand Forks, to be converted and smelted in conjunction with Granby ores. It is estimated that there is in sight approximately 400,000 tons of ore containing an average of 3½% copper besides gold and silver.

Spokane, November 4.

MEXICO

OAXACA

In the Santiago Minas, Tlacolula, Teojomnico, Ocotlan, and Zimitlan districts work is going on Steadily.——Recent finds have been made in various mines in the Taviche camps. Wm. Wallace reports shipping ore recently found in his mines; Fuos Bros. have bonanza again in the Veronica, Henry Hale in the Purisima, and J. A. Harreson in the Sanford. The latter reports a body of ore 35 metres wide from which he is shipping.——The latest news of interest received in this camp is that the long-expected custom mill, at Santa Inez Yazachi, near Ocotlan, is an assured fact and that the promoters will arrive in January to resume construction of this mill, which was started five years ago.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

ALFRED JAMES is in New York.

H. K. MASTERS is at Salt Lake.

W. S. NOYES has gone to Texas.

JOHN SPYER is at Zacatecas, Mexico.

C. H. LINDLEY has gone to New York.

D. E. BIGLOW is now at Berkeley, California.

F. W. BRADLEY left for New York November 8.

L. A. GREEN has returned to San Francisco from the East.

NORMAN C. STINES is expected in San Francisco November 25.

ERNEST A. HAGGOTT is spending November in Arizona on mining work.

F. M. SYLVESTER is now assistant general manager for the Granby Con. M. Company.

WILLIAM REA, formerly operating near Ketchikan, Alaska, is now at National, Nevada.

H. W. TURNER is returning from Korea and is expected in San Francisco in a few days.

GEORGE OTIS SMITH has returned from Europe and will visit California late in November.

R. OLIVER UDALL is mechanical engineer for the Santa Gertrudis company at Pachuca, Mexico.

W. G. PAGE, of Los Angeles, is at Salt Lake. He formerly operated in Wood River district, Idaho.

W. E. KING, of the Commercial Mining Co., operating at Rye Valley, Oregon, was at Salt Lake last week.

ERNEST GAYFORD, of the General Engineering Co., Salt Lake, has returned from Butte, Great Falls and Wallace.

FRANK A. BIRD, of the Bird-Cowan Co., Salt Lake, is engaged in making tests at the Edna mine, near Idaho City, Idaho.

J. R. H. ROBERTSON has been with the East Rand Proprietary Mines, Ltd., since June, when he returned from Rhodesia.

GUY A. R. LEWINGTON, of the N. A. T. & T. Co., has returned from Dawson, Y. T., and will be in San Francisco for the winter.

D. MACVICHIE and E. E. PRICE have joined under the firm name of MacVichie & Price to conduct a general mining engineering business with offices at 457 Newhouse building, Salt Lake, Utah.

JAMES C. H. FERGUSON, of the Midvale Steel Co., leaves this week for New York en route for a business trip to Brazil, Argentina, and other South American republics. He will be gone about four months.

BAILEY WILLIS has returned from South America, where he has assured the co-operation of Argentina, Chile, and Brazil in the preparation of the one to one million map planned by the International Geological Congress.

JOPLIN LEAD AND ZINC PRICES

Prices for blende in the district were the highest during October, since last March, running up to $49 per ton; and galena sold firm at $54 per ton. Calamine brought $24 to $26. Following are the shipments in pounds of zinc and lead ores during October, according to the *News-Herald*:

Joplin, blende, 2,876,930; lead, 216,790; calamine, 194,070; total value, $59,718. Webb City, blende, 4,970,280; lead, 602,180; total value, $122,808. Galena, blende, 1,322,030; lead, 85,140; total value, $30,649. Aurora, blende, 124,490; calamine, 156,810; total value, $4850. Granby, blende, 60,020; lead, 52,930; calamine, 172,570; total value, $4700. Carl Junction, blende, 140,780; value, $3150. Duenweg, blende, 314,000; lead, 790; calamine, 192,310; total value, $9653. Other districts, blende, 2,757,630; lead, 82,950; calamine, 290,580; total value, $99,209.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE FIGHT FOR CONSERVATION. By Gifford Pinchot. Pp. 152, 5 by 7, index. Doubleday, Page & Co., New York, 1910. Price 75 cents.

This is Mr. Pinchot's own statement of the plans and purposes of the movement with which his name is so closely associated. It is clear, concise, and temperate. It is as nearly fair as it is possible for a partisan to write, and should be widely read. It includes a general statement of the principles of conservation and strong arguments for their adoption. It should be in the hands of everyone interested in the movement.

A MANUAL OF PRACTICAL ASSAYING. By the late H. Van F. Furman, revised by William D. Pardoe. Pp. 530. Index. John Wiley & Sons. New York, 1910. Price $3.

This valuable and popular book, of which this is the seventh edition, has been completely revised and enlarged. The revising editor has entirely rewritten several chapters, particularly those on determination of silica, lead, copper, cobalt, nickel, and vanadium. A determination for uranium has been added, and also a method for analysis of commercial cyanide. Other important additions and changes have been made, notably in the chapters dealing with tin, antimony, bismuth, arsenic, sulphur, and tungsten. The work is once more up-to-date and its usefulness greatly increased.

MORE RECENT CYANIDE PRACTICE. Edited by H. Foster Bain. Pp. 418, Ill., index. *Mining and Scientific Press*. San Francisco, 1910. Price $2.

This book, which is a companion volume to 'Recent Cyanide Practice,' edited by T. A. Rickard in 1907, is just as good as its predecessor, and that is saying a good deal. The most striking thing about the book is the reputation and high standing of the contributors. Most of the articles contain a great mass of information on cyaniding which should be of great assistance to anybody interested in this branch of metallurgy. I often refer to 'Recent Cyanide Practice,' and I expect to do the same with the new volume. The only criticism I have to make is that some of the articles could very well have been left out, owing to the lapse of time since they were published. At the time they were correct, but in the interval the changes made in the plants have made them no longer good examples of cyanide practice. As an example, Rotherham's article on the Montana-Tonopah mill may be cited. That article was a striking one when published, and Rotherham's clear, concise style of writing pictured the mill admirably to the readers of the article. The *Mining and Scientific Press* was fortunate in being able to publish such an article. However, since then Rotherham has gone to South Africa and conditions have changed materially. The practice of today at the Montana-Tonopah is now different from that described in the book. So also with Mr. Parsons' article on the Desert mill, which now is so out of date that dismantling and building a new one in Tonopah is seriously contemplated. Mr. Hanson's article on the Silver Peak mill needs revision now. All these were admirable at the time of publication and are yet valuable as a matter of cyanide history, but in the sense of reliable data concerning modern practice, are misleading. On the other hand, such articles as E. E. Hersam's on 'Power in Crushing,' Kirby's communication, Burt's article on his filter, Boss on 'Ore Crushing,' Holt on 'Cyanidation of Silver Ores,' and many others will be of exceeding value many years from now. I want to congratulate the Editor also on retaining the little personal touches, such as the controversy over the El Oro tube-mill lining. Mr. Foote's letter is delightful, and reading these things livens one up to tackling with renewed vigor the heavy and somewhat dry but more useful other parts.

C. C.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

PRESCRIPTIVE TITLE TO MINING CLAIM

To acquire title to a mining claim by prescription it is necessary that the possession be hostile or adverse, and it must be open, exclusive, continuous, and uninterrupted for a period of five years under the statute of California, prior to the commencement of an action to contest the title. Any interruption of such adverse possession within the five years will prevent the acquisition of the title by prescription.

Big Three Mining & Milling Co. *v.* Hamilton, (Cal.) 107 Pac. 301. Jan. 1910.

PERFORMANCE OF ASSESSMENT WORK

In an action contesting the location of a mine and to quiet title to certain mining claims because of the failure to perform the required assessment work for a certain year, it was held that evidence that a mill put up on one of the claims was of no value for the purpose of reducing the ore found, was properly admissible as bearing on the question of good faith of the parties erecting the mill; but the question of whether or not the necessary improvement work done on the mining claim was not paid for was immaterial in such an action.

Big Three Mining & Milling Co. *v.* Hamilton, (Cal.) 107 Pac. 301. Jan. 1910.

LOCATION OF MINING CLAIM UNDER STATUTE OF 1897

A mining location made while the statute of 1897 was in force, but which was invalid for failure to comply with the provisions of that statute, may still be a valid location if the provisions of the mining laws of the United States have been complied with, and there were no intervening rights before the repeal of the statute of 1897, and where the claim had been occupied, held, and worked up to the time and after the repeal of the statute of 1897; and after tending to show that a claimant had from the time of the location continuously, up to and after the repeal of the statute of 1897, prosecuted and worked under a system tending to the development of the claim and other claims located by him in connection therewith, and that a part of such work had been done within the boundaries of the contested claim, was sufficient to establish possession of the entire claim to the extent of invisible boundaries.

Big Three Mining & Milling Co. *v.* Hamilton, (Cal.) 107 Pac. 301. Jan. 1910.

STATUTE GOVERNING LOCATION AND RE-LOCATION OF MINING CLAIM

Section 1 of the statute of Washington prescribes the duties of the discoverer of a lode in the location of a mining claim; section 2 of the statute requires the discoverer, upon filing notice of his discovery, to locate his claim by sinking a discovery shaft upon the lode to the depth of at least 10 ft.; section 8 provides that the re-location of forfeited or abandoned quartz or lode claims shall only be made by sinking a new discovery shaft and fixing new boundaries in the same manner and the same extent as is required in making a new location, or by sinking an original discovery shaft 10 ft. deeper than it was at the date of commencement of such re-location; section 9 provides that the provisions of the statute relating to the discovery shafts shall not apply to any mining location west of the summit of the Cascade mountains. In a contested location this statute was construed by the Supreme Court of Washington to mean that section 9 applied to re-location of forfeited or abandoned quartz claims under section 8 as well as to original locations, so as to excuse the sinking of a discovery shaft upon re-location of a forfeited or abandoned claim west of the summit of the Cascade mountains.

National Milling & Mining Co. *v.* Piccolo, (Wash.) 107 Pac. 353. March 1910.

Company Reports

BROKEN HILL SOUTH MINING CO.

The report of the Broken Hill South Mining Co., of Broken Hill, N. S. W., for the half-year ended June 30, 1910, has been received. The mine and plant were closed for nearly two months at the beginning of the year, owing to a coal strike in the mines of New South Wales; consequently the report represents the operations for but four months. During that period the ore hoisted and treated was 132,757 tons, containing by assay 15.2% lead, 6.4 oz. silver, 12.8% zinc. Over 99% of the ore mined was by contract. Development work totaled 1580 ft. Over 62,000 cu. yd. of filling was lowered into the mine, of which 20,406 cu. yd. was taken from surface quarries, 36,455 cu. yd. of tailing and 1831 cu. yd. of ashes being used in addition to 3449 cu. yd. of broken rock derived from development. There was employed a total of 1262 men. During the period covered by the report 52,548 tons of zinc tailing was delivered to the Amalgamated Zinc (De Bavay's), Ltd., under contract. During the half year a dividend of £20,000 was paid and another of like amount in July.

LA ROSE CONSOLIDATED MINES CO.

The La Rose Consolidated Mines Co., operating at Cobalt, Ontario, has issued its annual report for the year ended May 31, 1910. The report bears the date October 1. The report shows a production for the year of 3,170,028 oz. silver, which sold for $1,472,005.03. Following is a summary of shipments: Tons of ore shipped, 6,313,905; gross oz. silver, 3,100,443.93; gross silver value, $1,620,341.31; average price per oz., 52.261c.; sales of cobalt, $29,698.11; gross value silver plus cobalt paid for, $1,650,039.42; smelter deduction, freight, and charges, $208,065.33; net value received, $1,441,974.09. Mining and general expense was $448,153.60, or $70.76 per ton of shipping ore, and 14c. per oz. silver. Concentration cost $9.69 per ton of ore; depreciation, $1.49; marketing ore, $34.25; miscellaneous expenses, $0.36. The total net cost of production was at the rate of $116.50 per ton of ore. The estimated ore reserves are valued at 5,544,000 oz. In the operation of these mines, surface trenching to the extent of 5.16 miles was done. Drifting amounted to 5731 ft; cross-cutting, 3046 ft.; raising, 940 ft.; sinking, 342 ft., and stoping, 18,789 cubic yards.

NEVADA CONSOLIDATED

The report of the Nevada Consolidated at Ely for the year ending September 30 shows a net operating profit of $2,345,382, an increase over the preceding year of $699,320. Income from other sources, which includes the Nevada Northern railway, was $1,263,925, an increase of $673,326. Against the total income of $3,609,307 were interest charges of $28,520 and a previous inventory shortage of $125,489, leaving a net balance for dividends of $3,455,298. Dividends paid were $2,982,644, surplus carried forward was $472,654, previous surplus was $2,084,408, making a total surplus of $2,557,062. Production for the year was 62,772,342 lb., which averaged in price 12¾c. per lb. Copper costs for the year were 6.42c. per lb; after depreciation charges were entered, 7.05c. per lb. New tonnage developed during the year was 14,500,555 tons. During the year there was mined 2,236,434 tons of sulphide ore assaying 2.06% copper and 144,381 tons of silicious carbonate ore averaging 2.50% copper. It was expected that there would be some changes in the official roster of the company. A year ago when the Utah Copper Co. first made its offer of exchange, James Phillips, Jr., the president of the company, bore the brunt of a spectacular fight and by a narrow margin retained temporary control. It has been for a long time considered as certain that the Utah people were purchasing Nevada in the open market; their complete control was demonstrated at the annual meeting when Mr. Phillips resigned. The office of president has not yet been filled, but S. W. Eccles, the present vice-president, is mentioned as likely to become the company's executive head. Mr. Eccles is also vice-president of the American Smelting & Refining Company.

OIL DIVIDENDS FOR OCTOBER, 1910.

THE MINE & SMELTER SUPPLY Co., New York. Bulletin No. 5. Third Edition, September 1910. 'The No. 5 Wilfley Concentrator.' Complete details concerning the timber frame model of this well known table. Illustrated. 20 pages. 7 by 10 inches.

A. LESCHEN & SONS ROPE Co., St. Louis. 'Across the Rio Grande.' An unusually attractive and interesting book descriptive of a recent tramway installation across the Rio Grande connecting this country with Mexico. The tramway is the property of the Del Carmen Mining Co. of Boquillas, Coahuila, Mexico, and is used for transporting zinc ore from the end of a five-mile wagon haul, through some very rough country, across the river to a point in Texas, from where it is hauled 90 miles in wagon trains drawn by traction engines. The tramway itself is 31,500 ft. long. It is equipped with 90 buckets, each carrying 600 lb. of ore and traveling at the rate of 300 ft. per minute. Each track rope is divided into five sections with a tension station weight box at one end of each, the other end being anchored. The weight boxes maintain proper tension under the working strain and against variations in length, due to stretch and changes in temperature. The buckets load and dump automatically, and it is said very little power is required for the operation of the tramway.

COMMERCIAL PARAGRAPHS

The ALBERGER PUMP Co., New York, announces that Braun, Williams & Russell, Inc., 503 Market street, San Francisco, has recently been appointed its Pacific Coast selling agents.

The PACIFIC TANK & PIPE Co. has just completed an office building adjoining its Portland factory, and hereafter the Portland address of the company will be Kenton Station, instead of 210 Wells Fargo building.

THE MINING SUPPLY Co., 64 Broad street, New York, has taken the sole foreign selling agencies for the James ore concentrator table and for Krom rolls, crushers, and screens. Among other interesting facts contained in two attractive circulars recently issued is the statement that 70% of concentrating tables in use in the mills at Cobalt are James tables.

The firm of SMITH & LAIRD, mining engineers, of Bisbee, Arizona, has been dissolved by mutual consent and the name changed to Smith & Ziesemer. Ralph A. Ziesemer, mining engineer, is associated with Franklin W. Smith in the new firm, which retains the same offices and address. George A. Laird continues as manager of the Candelaria Mining Co. of San Pedro, Chihuahua, Mexico, which position he has filled for more than two years.

Under the name of the MCKIERNAN-TERRY DRILL Co. there has been a consolidation effected between the McKiernan Drill Co. and the Terry Core Drill Co. The new company will continue to manufacture the lines produced by the two companies it succeeds, and it is understood that the union of their organization will result in largely improved manufacturing facilities, with consequent better service to purchasers. The various lines manufactured by the McKiernan-Terry Drill Co. include rock, hammer, and core-drills, coal cutters, sheet pile drivers, and compressors. The address of the company is 115 Broadway, New York.

Market Reports

LOCAL METAL PRICES.

San Francisco, November 10.

Antimony	12—12¾c	Quicksilver (flask)	45½—46

EDITORIAL

IN estimating the importance of the recent troubles in Mexico it is well to keep in mind that there are those who believe their political ambitions would be served by discrediting President Diaz. One of the most effective ways of bringing this about would be to involve his administration in foreign difficulties. It is significant that what began as a peaceful and proper protest on the part of students, became an outbreak on the part of a rabble.

CONSERVATION is discussed in this issue by Mr. C. W. Hayes, who, as chief geologist of the United States Geological Survey, has had unusual opportunities to study the problem of conserving our natural resources. In his address, originally delivered at the University of Chicago and presented here in a slightly condensed form, Mr. Hayes has treated the matter in a notably sane and informing manner. Such discussion is helpful, and we especially commend the article to our readers.

THE TENNESSEE COPPER COMPANY has an excellent reputation for pioneer work in developing mining and metallurgical methods. While the ore that is handled is low in copper content, the company is fortunate in that the mine is situated where it is possible to sell the sulphuric acid manufactured as a by-product. Making acid, however, out of the lean gas available has involved many difficulties which have been met with distinguished success. We print in this issue a general account of the work of the company, written by Mr. Karl R. Morgan, one of the younger American mining engineers, now in Mexico, but who had the opportunity of visiting and studying the work at Ducktown. That he used his opportunity well is evident.

THE MACHINE-DRILL competition lately completed at Johannesburg in the Transvaal has attracted little notice in this country. The local Chamber of Mines offered a money prize for the best drill, suitable for working in the comparatively narrow stopes of the Rand mines. This prize was afterward supplemented by the Government, and the total money offered amounted to £5000. The conditions were severe, but there were 23 entries, including a number of drills of American make. After the elimination trials the number competing was reduced to 10. Only 4 drills completed the allotted tasks, none of them being American, and it would be interesting to know from our countrymen why they did not continue. It seems strange that manufacturers who were the pioneers in this field of industry played such a small part in this important contest. In numerous

contests held in the United States and in actual work, American drills have established enviable records.

TENABO is the name of an old mine in Lander county, Nevada, that in years gone by was a heavy producer, but which has long been idle. Recently the Tenabo Mining & Smelting Company was organized to reopen the property and a disastrous attempt was made to sell its stock on the New York Curb. Now it is announced that an effort will be made to interest French capital. This is not likely to succeed, but it will make it more difficult than ever to enlist French support for the really good American enterprises. Reopening old mines and developing new ones are legitimate undertakings and greatly to be encouraged, but such work involves an element of risk that is foreign to the ways of French investors, and, since of any number of such enterprises a large proportion prove failures, it induces a general skepticism as to American securities among those who might otherwise be heavy investors. Manhattan Consolidated, Utah Copper, United States Steel Common, to cite but three American stocks recently sold in France, are conspicuous examples of stocks of speculative value. At least one of these was sold under what amounted to misrepresentation. Since American mining enterprises need additional capital and the French with much to invest are willing to accept a low rate of interest, it is a pity that they are offered the speculative rather than the assured stocks. The inevitable result is to spoil a good market.

California Mining Bureau

The excellent report upon 'Gold Dredging in California,' written by Mr. W. B. Winston and Mr. Charles Janin, calls sharp attention to the possibilities of usefulness inherent in the State Mining Bureau supported by California. As is well known among mining engineers, the Bureau, under its present chief, has been for several years a singularly useless, not to say harmful institution. That it has now published a valuable report on one of the most important industries of the State is due less to the gentleman whose name appears conspicuously on the cover than to the authors whose names are printed in modest type inside the work itself. The dredging companies have most generously given full data both as to costs and technical performance, but the main credit for the work must go to Mr. Winston and Mr. Janin. It is but fair that their fellow engineers should know that one of the gentlemen received nothing for his services, and the other only the most modest compensation. The work has been carried out with fine professional spirit as something of benefit to the industry, but it is hardly appropriate that a rich State such as California should accept gratuitous professional services when efficient management of its departments would make this unnecessary. Closer attention to printing bills, to efficiency in the work of regular employees, would work marvels of economy. The Governor-elect, Mr. Hiram Johnson, has given solemn pledges to clean up the State government. He starts in unhampered and with the enthusiastic support of a great people. We hope he may enjoy every success, and, incidentally, we invite his attention to the conduct of the State Mining Bureau under the administration of the present State Mineralogist. Here is something which touches directly the first great industry of the State, the one that gave it being and one that makes annually an enormous contribution to the wealth of the State and Nation. The position of State Mineralogist should be filled by a competent technical man who has the confidence of his professional associates. It should no longer be treated as one of the spoils of politics. Do the work right or abolish the office.

Mexico and the United States

Accounts of the recent rioting in Mexico have been read with particular interest by mining men. A large portion of the Americans living in Mexico are connected with mines, and American investments in mines and smelters are especially important. To our professional brethren in the Republic of Mexico we extend every sympathy in these trying times. It is hard that they should suffer because of the reckless and cruel act of a Texas mob. It is, however, a law of life that cruelty begets cruelty, and punishment falls often on the innocent. It is a time for great patience and restraint on both sides of the line. Fortunately the disgraceful excesses in the City of Mexico and in Guadalajara, as well as in Texas and Oklahoma, are but the expression of an unthinking minority. Between the American and Mexican peoples there has long been the greatest mutual respect and good-will. The officials of the two governments are doing everything possible to allay apprehension and to preserve these cordial relations, fortunately with every prospect of success. It is striking that, despite the natural antagonism that seems always latent when two races are brought together, despite the fact that the majority of the Mexicans in the United States are poor men occupying subordinate positions while most of the Americans in Mexico go as investors or representatives of investors, and so in their daily work give orders to numerous Mexicans in their own country, despite certain historical clashes, there has been so little friction between Mexico and the United States. It is scarcely less striking that with all the lurid accounts of the riot that have been sent broadcast, there is no talk of reprisals or of war. This is due to the long continued and intelligent efforts of the officials of the two countries, and especially of those of Mexico. It is also due to the fact which thinking Americans must recognize, that in this affair we are deeply in the wrong. It is expected that the Mexican Government will effectively protect the Americans in Mexico, and it is believed that it will do so, but in the United States the national government is practically powerless to protect Mexicans or any others, including its own citizens, against mob violence. Preservation of the peace is a function of the State and local governments, and when local public opinion in any district condones the act of a mob, as it often does there is small chance of bringing any one to justice. By quick and determined action a sheriff can nearly always save a threatened prisoner, but the sad fact is

that in districts where mob violence reigns the sheriff is usually in sympathy with the mob. It is difficult to see any prompt and effectual remedy. Education and the slow growth of a sound public opinion will eventually cure the evil as it has in older countries. In the meantime foreigners living in the United States but take the risk that its own citizens must face. Inasmuch, however, as our Government exacts from other countries scrupulous protection of Americans it is right and proper that similar protection be given in America to foreigners, even if we do not care for it ourselves. Fortunately there is ample constitutional authority for doing so. The constitution makes treaties part of the supreme law of the land, and the late president, Benjamin Harrison, himself a recognized expert in the law, recommended that Congress enact such legislation as would place in the hands of the Federal Courts the enforcement of treaty obligations. That this would effectually cure the evil is believed by nearly every intelligent student of the subject. It is well recognized that a man or a community that will take violent liberties with laws that must be enforced by local judges and by peace officers elected from the community itself, will be scrupulous in observing the Federal law and regulations. It is not severity but certainty of punishment that makes for law enforcement, and the Federal courts have an enviable record in the matter of dealing with crime and criminals. The law recommended by Mr. Harrison has been repeatedly introduced in Congress, but has never been seriously considered. It ought to be promptly passed.

What is Coal?

It has long been customary to rate coals upon the basis of a proximate analysis, including determination of the percentage of moisture, ash, fixed carbon, and volatile 'matter' or 'combustible.' If to this, determinations of the sulphur and the number of heat units were added, it was felt that all the information the most exacting engineer could ask, had been furnished. This method of analysis had the virtue of simplicity, the determinations were easily and cheaply made, under standardized methods fairly concordant results were possible, and the information furnished really was adequate to many of the needs of the engineer. Fortunately, or unfortunately, according to the point of view, there are always inquisitive chemists, and some of these refused to accept such simple analyses as sufficient. Engineers found, too, that the proximate analyses in many cases failed to give the data upon which coal could be properly rated, and even at times led to the rejection of coal found on trial to be excellently suited to some particular use. The modern campaign against smoke, the desire for greater efficiency in burning, the development of the gas-producer and the gas-engine, have all co-operated to stimulate the search for better methods of coal analysis. The ultimate analysis, in the course of which carbon, hydrogen, nitrogen, sulphur, and other elements are determined and the residue set down as oxygen, failed to satisfy this want. It was quickly found that not only the elements in the coal, but their form of combination must be known in order to use an analysis to determine its value for a special purpose. When chemists were asked just what coal is, they were unable to answer, but professed entire willingness to attempt to find out. Many men went to work on the problem, particularly, in the United States, Mr. N. W. Lord at Ohio State University and Mr. S. W. Parr at the University of Illinois. It was Mr. Parr who showed that the volatile matter in coal was by no means all combustible, but that some of it was not only inert but anti-calorific. Gradually the conception of coal as a solid solution of hydrocarbons, roughly comparable to the liquid solution represented by petroleum, came to be developed. German chemists were first to attempt analysis of coal by dissolving out successively the different hydrocarbons, a method that while yet imperfectly developed shows distinct promise. Both in Germany and in the United States research was undertaken along the line of destructive distillation at low temperatures, and results were obtained that have been of great interest, particularly to gas manufacturers, and may prove to have important bearing on the problem of coking dry coals. The work of the United States Geological Survey, beginning with the coal-testing plant at St. Louis and continuing with the organization of the Technologic Division, now become the United States Bureau of Mines, greatly stimulated these researches on coals. The Engineering Experiment Station and co-operating departments at the University of Illinois formed a second centre of research. Mr. Lord for the Government, Mr. Parr for the State, with their numerous and active assistants, have in a short time developed a fairly enormous amount of new data on coal. It is appropriate that the first bulletin of the Bureau of Mines should have for its subject 'The Volatile Matter of Coal' and should treat the subject in a scholarly and scientific manner that augurs well for the character of the succeeding bulletins of the series. The authors, Messrs. Horace C. Porter and F. K. Ovitz, were trained under Mr. Parr and worked under Mr. Lord, and they have accordingly had the benefit of criticism from both men. They confirm the conclusion of Mr. Parr that a considerable portion of inert material exists in the volatile products of coal and show that the amount and composition are specific characteristics of each type of coal. They find that there are comparatively large percentages of carbon dioxide, water, and other inert materials in certain Western coals; that large amounts of the higher methane hydrocarbons are distilled at moderate temperatures, particularly from Appalachian coals; that the younger Western coals yield, at moderate temperatures, quantities of gas and tarry vapors. These facts have direct bearing on the smoke-producing tendencies and the adaptabilities of the various coals. The studies also afford much data for further scientific research, though they do not as yet permit an exact definition of coal itself. They furnish a basis for intelligent experimental work with furnaces, gas-producers, and coke ovens, that is sure to yield important economic results.

The Conservation Movement

By C. W. Hayes

Any attempt to evaluate contemporary events and personages is an extra hazardous undertaking. Events, however, have been moving so rapidly in the past few years that it may be possible to obtain a reasonably correct perspective, to reduce them to their proper proportions. Few subjects have occupied a larger share of public attention during the past three or four years than the subject of conservation. However much the term may have been overworked, and whatever extravagances may have been committed in its name, it is a most significant and encouraging fact that the American people are awakening to the urgent necessity of systematic action. This promises a saner and more permanent industrial development. In its popular aspect the conservation movement began with the calling of the first Conservation Congress in 1907, but it will be easily understood that its real beginning must be sought much farther back than this. There was a long period during which a gradually increasing number of thinking men were recognizing more and more clearly the extravagance attending the use of natural resources, and were collecting information as to the extent and value of these resources. These ideas began to assume definite form and to find occasional expression near the middle of the last century. They grew steadily with the rapid growth in industrialism and the consequent increasing demand for raw materials, with the change from small units of production widely distributed to a few large units highly concentrated. Among the many agencies which brought the country into a condition of preparedness for the movement a few may be mentioned.

1. The earliest of our natural resources to be seriously depleted was timber, chiefly because of habits inherited from generations of pioneers to whom the forest was simply an obstacle to be overcome and destroyed. It was natural, therefore, that the Forest Service from its beginning should have consistently and actively urged the importance of conservation, chiefly of the forests, but of other resources as well. The passage of the law in 1901 providing for forest reserves, was due largely to the influence of the Forest Service, and gave practical and concrete effect to its efforts. The results of the investigations and of the educational campaign carried on by the Forest Service have extended to privately owned forests, and many large lumbermen have abandoned the wasteful methods which were formerly universal.

2. With the rapid filling up of the agricultural lands in the West the necessity for utilizing and so conserving the waters of the arid regions became pressing. The possibilities of irrigation, first clearly and forcibly pointed out by J. W. Powell in 1878, were realized through the enactment of the reclamation law in 1902. Thus a second great agency for the cultivation and dissemination of conservation ideas was developed in the Reclamation Service.

3. While mechanical engineers during the nineteenth century had brought the steam engine from an extremely crude and lowly beginning to a high state of efficiency, the question of increasing the power obtained from every pound of fuel used had received relatively little attention. Highly important, therefore, was the series of investigations inaugurated by the Geological Survey at the fuel-testing plant in connection with the St. Louis Exposition. The Technologic Branch of the Survey under which this work has been carried on, and which is now the Bureau of Mines, has been another effective agency for preparing the way for conservation ideas.

4. The organic law of the U. S. Geological Survey enacted in 1879, specifies as one of the duties of that bureau the "classification of the public lands." For reasons which need not be given here this eminently wise provision of the law was 'more honored in the breach than in the observance' until 1905, when work was started in southwestern Wyoming for the specific purpose of classifying the land. This work was so fruitful of results that it was greatly expanded the following year. Largely through the experience thus gained and the recommendations based on this experience, the policy of withdrawing coal land from entry pending classification and valuation was adopted. The officers of the Survey believed that the authority to withdraw coal lands from entry pending classification and valuation was necessarily implied in the existing coal-land law, but they also believed that this executive authority should be employed conservatively and only for the express purpose stated in the withdrawal; that it should not be employed to accomplish other objects, however desirable in themselves those other objects might be. In this the Survey was temporarily overruled, and large areas of land were included in the 1906 withdrawals for which there was never the slightest justification. However, in spite of mistakes due rather to excess of zeal than to any bad motive, the policy of land withdrawals has been both a powerful agency for educating the public and an effective means for accomplishing practical conservation. Applied at first only to coal lands it has subsequently extended to oil and phosphate lands and to water-power sites, and through the recently enacted legislation the question of the legality of the withdrawals is entirely removed.

By means of these agencies and many others less prominent, but none the less effective, public opinion was educated to the point where only the dramatic touch was needed to make conservation a popular national movement. This touch was the President's call for the famous White House conference in 1907. The meeting of thirty-four State governors and many distinguished scientists to discuss the conservation of our natural resources, was sufficient to attract and fix public attention as nothing else could possibly have done. The first conference dealt largely in glittering generalities, but it made possible the one in 1908, at which a great mass of facts bearing on the subject was presented by the best qualified experts in the country.

The second period in the movement was brief and

dramatic. It extended from 1906 to 1908, covering the two Washington conferences. It was the time of popular awakening to facts and conditions long familiar to a few, but coming to the mass of the people as something entirely new. This period was characterized by more or less sensationalism and hysteria. Much truth was disseminated, but along with it was much misinformation and many half truths. It accomplished the extremely important result of fixing public attention, but it was merely a temporary and passing phase of the movement.

The third period is just being entered. It has been characterized thus far chiefly by unfortunate recrimination and denunciation. Like most other articles of faith, conservation means many widely diverse things to different men. A clear definition of the term, a formulation of creed, is therefore a necessary preliminary to the discussion. Disregarding the views of the extremists and visionaries we may define conservation as **utilization with a maximum efficiency and a minimum waste.** Please note that I lay special stress upon **utilization,** for I regard it as an essential feature of any form of practicable conservation. To conserve resources for future generations at a serious sacrifice of the interests of the present is not only unwise, but is wholly impracticable and visionary. To be effective, therefore, conservation measures must rest upon an economic basis; to secure the adherence of an interested party they must appeal to his business sense as offering distinct material advantage. Thus the arguments for conservative forest management of privately owned forests were absolutely without effect until it was demonstrated that such management offered larger profits than the practice in use. Likewise it is useless to urge a coal operator to mine out all the coal in a bed if by so doing he runs his mine at a loss. Only the inducement of economic advantage, of increased profits, will be generally effective.

There appears to be an unfortunate confusion in the minds of certain advocates of conservation. They have apparently confused conservation of natural resources with destruction of the trusts, and the mixture has resulted in pure demagoguery. Unquestionably both subjects are highly important, but they have no necessary connection, unless indeed they are antagonistic. The natural resources will not be conserved by destroying the trusts, nor will the trusts be controlled by checking the waste of natural resources. Anyone who has studied conditions attending the development of mineral deposits must have been impressed by the fact that those deposits held by large companies are being developed and utilized with a view to prevention of waste, in accordance with the principles of conservation, to a much greater extent than are the deposits held by small companies or by individuals. The explanation is purely economic. The large company can introduce at a profit methods for preventing waste which would be ruinously expensive to the small operator, and furthermore the soulless trust is immortal and must provide for its continued existence far beyond the ordinary lifetime of the individual. Hence the [illegible] conservator of our natural resources is the trust. I am aware that this is rank heresy in certain quarters, and that my statement is liable to be misunderstood and distorted, but the sooner we recognize clearly the antagonism between conservation and destruction of the trusts, the sooner we shall be in a position to solve the problem wisely and fairly.

It is obvious that the term 'natural resources' covers a wide field and that from the viewpoint of conservation they admit of classification into a number of widely separated groups. The type of the first group is water-power which is conserved only by utilization, and is best conserved when it is most fully developed and used. In this group are wind-power and the radient energy of the sun. Since water-power cannot be conserved by hoarding, its early and complete utilization in the most efficient manner possible is clearly the end to be sought. The second group includes forests and soils which are renewed under favorable conditions, though slowly, and to yield the largest benefits must be used continuously, but are liable to serious depreciation and waste through improper use. Here the problem is obviously to balance the use against the renewal so that the resources suffer no permanent depreciation. The third group includes minerals which once used are never renewed, but are gone forever. A further subdivision of the useful minerals is necessary into two classes, inexhaustible and exhaustible. Of these the first includes those minerals which occur in nature so abundantly and so widely distributed that no conceivable use will materially diminish the visible supply; such are salt, limestone, clay, sand, building stone, and in general minerals used as structural materials. The second class, the exhaustible minerals, includes those which, although in many cases they occur in very large quantities, nevertheless are definitely limited in distribution and amount; such as the fuels—gas, oil, coal, and lignite; the metalliferous ores, sulphur, and phosphate.

It is this latter class, exhaustible minerals, with which the problems of conservation are chiefly concerned. Here it is necessary to weigh present demands against future needs, and to devise methods of utilization which shall neither sacrifice the interests of the present nor entail unnecessary hardship on future generations. This can be accomplished in general, by utilizing the minerals (1) for the purpose for which they are most valuable, (2) in the manner that will secure the most efficient results, and (3) in the locality where the greatest economies can be effected.

Let me illustrate by a concrete example. Natural gas is the ideal fuel and source of power, but by reason of its unstable and fugitive nature is the mineral most likely to be seriously wasted and first exhausted.

In this connection the history of natural-gas development in the United States is instructive. Its discovery has in every case been incidental to the search for oil, and it has always been at first regarded as an unmitigated nuisance by the oil driller. For many years in the exploitation of the great Appalachian oilfields in Pennsylvania and West Virginia it was permitted to go to waste until its enor-

mous industrial value was discovered. Now, however, an intrieate system of pipes reaehes out over this region, and from every well that will yield an appreeiable amount, the gas is pumped and turned into the great arteries which furnish a supply of fuel and power to the manifold industrial establishments of western Pennsylvania and eastern Ohio. Moreover, additional supplies are being sought through the drilling of new wells, and the seareh for gas is as eager as it has ever been for oil. This notable change has been brought about in part by legislation, but chiefly by intelligent eo-operation between the large gas companies and the oil producers induced by the decreasing quantity and increasing value of the gas. In 1885-6 the great gasfields of Ohio and Indiana were discovered and the same disgraeeful history was repeated: First there was unehecked waste, then extravagant use with the belief that the supply was inexhaustible; finally eame the reeognition of the unwelcome fact that the supply was strietly limited, and with it eeonomical utilization and development under wise legal regulations. A few years later the Kansas-Oklahoma fields were discovered, and there the same history was in a measure repeated, although the value of the gas was more promptly appreciated and the industrial development was correspondingly more rapid. In all of these fields except Oklahoma, the maximum yield has probably been passed, but the industries that were established by reason of the exeeptional indueements offered by the abundant supply of cheap fuel and power, remain as permanent sourees of wealth to the eommunities whieh were sufficiently energetie to take advantage of their opportunities.

The industrial possibilities afforded by the great supplies of the most perfect fuel and souree of power in nature tax the imagination, but the realization of these possibilities depends on the applieation of the fundamental conservation principles stated above. The gas must be utilized (1) for the purpose for whieh it is most valuable, (2) in the manner that will secure the greatest efficieney, and (3) as near as possible to the point of produetion.

1. The most valuable use for natural gas is in the development of power. It is estimated that with gas at 12c. per thousand, electric-power ean be developed as eheaply as it ean be generated by water-power at Niagara. But a quarter of this priee or 3e. per thousand would be a highly remunerative priee for the gas in northern Louisiana. It follows therefore that electric-power can be generated in this region at one-fourth the eost at Niagara.

2. Experiment has shown that the amount of gas required per hour for the development of one horsepower varies from 9 eu. ft. with the highest type of large internal combustion engine to 130 eu. ft. with the ordinary steam engine. In other words, the efficieney of the gas is over fourteen times as great when used in gas-engines as when used for generating steam under the boiler. This leaves no possible question as to the manner in which the gas should be chiefly utilized.

3. The methods of transporting natural gas through pipe-lines and the long-distanee transmission of electric-power have been brought to a high state of efficieney in the past ten or fifteen years, but they still involve an expensive plant which must be paid for and maintained by the consumer. Thus if the gas were piped from northern Louisiana to St. Louis it would probably require the expenditure of four to eight units of the gas to deliver one unit to the consumer. In other words, if used in St. Louis the effieiency of a given production would be between one-fifth and one-tenth as great as if used at the point of production. To utilize the power which the gas now eseaping in Louisiana is capable of generating would, of course, necessitate the development of great industries where none now exist. But there are no physieal reasons why they should not be developed, since the necessary raw materials are close at hand. These raw materials are the coal, sulphur, salt, limestone, clay, sand, and gypsum and the ores of aluminum, manganese, and iron, whieh with a cheap souree of power, are the essentials of the principal ehemical and metallurgical industries. Some of these raw materials, as the sulphur, salt, and bauxite, are now being mined and transported to distant points where cheap power is available, as at Niagara Falls, and in the natural-gas fields of Kansas, Indiana, and Pennsylvania. Thus the utilization of the natural gas near its point of origin would not only greatly inerease the effieieney of the gas, but would effect equally great increase in efficiency in the utilization of many other mineral resources. The point which I wish to impress is that the increase in cost of raw materials due to unneecssary transportation to distant points of manufacture is just as much a waste of the raw materials as though a certain portion of every ton mined were dumped into the sea. It is even worse than that, for in many cases the unnecessary transportation is expended on inexhaustible minerals, such as limestone, clay, and salt, but it is at the expense of an exhaustible mineral—coal.

The prineiple that all substances shall be used for the purposes for which they are most valuable involves the substitution of the more abundant or inexhaustible for the less abundant or exhaustible, subject always to the factor of location. Examples of praetieal conservation effeeted by this means are the substitution of water-power for steam, of eement for wood and iron in eonstruction, of peat and lignite for development of power by means of the gas-producer and gas-engines in place of high-grade coal under the boiler, of producer-gas from lignite in plaee of coke from high-grade coal for metallurgieal operations, and many others might be cited.

The seeond half of eonservation as before defined, is utilization with minimum waste, and in the case of mineral resources there are preventable wastes in extraction, in preparing for use, and in transportation. The extent of the waste from these sources and the extent to which it is preventable vary widely in case of different minerals, and the means that must be employed for preventing the waste are correspondingly varied. The greatest percentage of waste is in connection with the development of natural-gas fields, and it is probably safe to say that taking all of the fields together, much more gas has

been wasted than has been usefully consumed, probably many times as much. From this extreme the percentage of waste decreases practically to zero in case of some of the metalliferous ores having high unit values. In the case of coal it is usually counted that for every ton mined half a ton remains in the ground in such shape that it can never be recovered. With coal there is an added waste in preparing for market, as is evidenced by the enormous accumulations of slack and culm at modern coal mines. In general there are two ways in which this waste may be prevented or reduced; first by the exercise of the police power of the State, and second by the development of industrial conditions which shall make it profitable to reduce the waste. The field within which legal remedies for prevention of waste are applicable is very restricted—practically to those cases in which the acts of one individual may seriously injure the property of his neighbor, that is, to the development of oil and gasfields. For example, if I own a forty-acre tract of coal land, it is little, if any, concern to my neighbor or the public generally what I do with it; whether I choose to leave the coal in the ground or to mine it economically or wastefully. If, on the other hand, I own forty acres in a gasfield, the case is entirely different. I may drill a well of which I lose control through carelessness or ignorance so that it not only destroys my own property, but also that of my neighbors. In an oilfield a careless driller may admit water into the oil-bearing stratum from above or below, and greatly damage the productiveness of a large area. Thus the entire community may be injured through the acts of a single individual. His acts then become a matter of public concern and a proper field for legislative control. This has been generally recognized and nearly all States having important oil and gas resources either have already enacted laws regulating their development or have such legislation under consideration.

Legal remedies for the prevention of waste are, however, at best only to be regarded as emergency measures, useful at first to control the situation until the necessary public opinion can be developed and afterward for the control of the small percentage of operators who are too selfish or shortsighted to heed public opinion. The real and permanently effective control must come through the operation of economic rather than statutory laws, through the development of local industries in a gasfield, for example, which shall make the gas so valuable that no operator can afford to waste it and no community can afford to permit waste to continue. In the development of the more bulky minerals such as coal, iron ore, bauxite, or phosphate, waste is due chiefly to two causes, first, unrestricted competition, and second, distance from point of production to point of utilization. The coal operators in the Pittsburg district recognize that the coal in that district is limited in amount and that at the present rate of production it will be exhausted at no distant date. They recognize that present mining methods are extremely wasteful, only the best grade of coal being mined and half a ton of that being left in the ground for every ton taken out. But they also recognize the fact even more clearly that under present conditions of keen competition and narrow margin of profit, no other method of mining is possible except at a loss. If all of these operators could combine and increase the price of coal a few cents on the ton, and at the same time market a slightly lower grade fuel, they would be able to reduce the waste to insignificant proportions, a result which certainly a large proportion of the operators are anxious to secure, since it means longer life to their mines and greater aggregate returns on their investment. In this connection one point must be emphasized which is wholly ignored by many of the most ardent advocates of conservation. It is that conservation of our natural resources means immediate higher cost of raw materials and consequently of finished products to the consumer. Whether prevention of waste is secured by legislation, by public opinion, or by combination and elimination of competition the consumer must pay for it. This increased cost due to the prevention of waste should eventually be offset by economies due to more efficient utilization, but this effect will not be immediately apparent. As illustrating the second source of waste, distance from point of production to point of utilization, take bauxite and phosphate, both of which are among the exhaustible mineral resources. The mineral bauxite forms the basis of three important industries, namely the manufacture of metallic aluminum, of alum, and of alundum, or artificial corundum. It has thus far been discovered in commercial quantities in this country only in the Southern States—Georgia, Alabama, and Arkansas. Since the mining of bauxite began in 1889 about 600,000 tons of the mineral have been produced, and every ton has been shipped to points in the vicinity of Chicago, Pittsburg, and Niagara Falls. The manufacturers at these points demand a certain grade of ore, since the lower grades will not bear the cost of transportation. Thus the silica must run below 10%, since silica, while not otherwise injurious, is so much dead weight on which freight must be paid. But a large proportion of the ore in most of the deposits contains more than the allowable percentage of silica. These portions of the deposits are therefore not marketable under present conditions, and are left in the mine or thrown on the dump and lost. If the manufacturing plant were located near the mines this low-grade ore could be utilized and the average cost of mining greatly cheapened. By passing it through the first process of manufacture a ton of ore having a value at the mine of about $4 is converted into products weighing only a fraction of a ton, but having a value of from $50 to $175; and these products easily bear the transportation charges to distant points of consumption. Phosphate, like bauxite, has thus far been produced in commercial quantities only in the Southern States, and by reason of cost of transportation the manufacturers of fertilizers have insisted upon a grade of rock containing not less than 65 or 70% lime phosphate. But the Tennessee deposits contain a large proportion of 40 or 50% rock, and in most cases this is wasted in mining the marketable material. At the present

increasing rate of consumption there is no question that within a comparatively few years these deposits will be so far depleted that rock containing as low as 40% lime phosphate will be in demand.

I have shown that mineral deposits cannot be generally utilized with the highest effieiency by the small owner, or held in reserve for the future so effectively as by the large owner—in other words, by the trust. Following the same line of reasoning, it is evident that the Government can still more effectively provide for future needs by a wise conservation policy applied to the administration of the mineral resources remaining in public ownership. I should by no means advocate a policy of hoarding these resources regardless of present needs. The Government still retains the title to about 60% of the coal land in the Western public-land States. It can afford to capitalize the value of this land at a lower rate of interest than any individual or trust and therefore the consumer of coal a hundred years hence will get cheaper coal if the Government retains ownership than if it passes into private hands, even if the private holder realizes only a fair and reasonable return on his investment. The policy of the Government in relation to its coal lands should be, therefore, to sell these lands at a price suffieiently low to permit development in response to present demands, but so high as to discourage speculative buying for the future. Fortunately, it is now possible to carry out this policy since a law enacted at the last session of Congress permits the separate disposal of surface and mineral rights. Coal deposits can be held by the Government until they are actually needed for mining, while the title to the surface may be disposed of at once for purposes of agriculture and grazing.

The Government also retains the ownership in large areas of valuable oil, gas, and phosphate lands. The conditions with reference to these lands is much less satisfactory than in the case of the coal, for while they are withdrawn from all disposal pending classification, this classification and valuation will accomplish little good unless the law for their disposal is revised. Oil lands are now disposed of under the placer law which is absurdly inadequate to protect either the interests of the Government or of the oil man. In case of the phosphate lands no man knows whether the lode or placer law applies and practically all claims entered previous to the present withdrawal have rival claimants, each doing assessment work and each hoping to secure a patent. The one thing certain in the case is that it is due to yield a prolific crop of litigation. For both oil and phosphate lands a system of leasing is strongly urged. In the case of oil the argument for such a system rests on the unstable and migratory character of the oil by reason of which it cannot be sold like coal in terms of acres, but must be sold as a commodity and only after it reaches the surface where exclusive title to the product is first acquired. The argument for a leasing system applied to the phosphate deposits rests on wholly different grounds, but is equally strong—it is the necessity for regulating the development of these deposits so as to prevent the export of the product on which the future agriculture of the country directly depends.

I have endeavored to outline briefly the trend and status of the conservation movement, to define the conservation problem, and to indicate some of the means through which the desired results must be attained. The problem is an exceedingly complicated one at best and admits of no simple solution. Its solution will certainly not be promoted by throwing it into the political arena or by using it to advance the political fortunes of any individual or party. In its last analysis it is a problem of education. Its solution is dependent upon the dissemination of sound information, the cultivation of logical thinking, the development of sane action. It is not enough that the engineers, scientists, and college professors should be fully informed and alive to the necessities of the situation. The great mass of professional, business, and laboring men and women must be brought to realize that each one has a vital interest in the subject, that so long as our natural resources are not utilized in the most efficient manner possible each one is suffering a direct loss in his material prosperity and opportunities. An excellent start has been made, but much remains to be done. The greatest obstacle to the conservation movement is ignorance, and it must be overcome by a serious systematic campaign of education.

The first cyanide mill in the Black Hills was built at Deadwood in 1892, and it at once became apparent that, whatever might be accomplished by barrel-chlorination, the cyanide process was peculiarly adapted to the treatment of these ores which had so long defied the best metallurgists of the country. Other cyanide mills were built and in every case proved a success, although adopting different methods. Some crush dry, others wet, and still others in cyanide solution, but all operate successfully, and as a result the silicious ores of the Black Hills have produced to date not less than $30,000,000, and there still remain large bodies of ore untouched, aside from the probability of finding much that is unknown, for the area in which these silicious ores occur is large and in some portions developed or prospected to only a limited extent, particularly in the region on the north side of Custer peak, and extending northwesterly around the south side of Terry peak, to and beyond the canyon of the Little Spearfish.

The quarries of Maine supply immense quantities of stone, especially granite, for use in all parts of the country, but the ores of the State are not now extensively mined. For many years the ores of Mount Katahdin yielded 2000 to 15,000 tons of iron per year, and in the early sixties the Lubec and other lead mines were worked in a small way. In the eighties several hundred tons of copper was smelted at Bluehill from ores mined at the Douglas and other mines in the neighborhood. In addition to this metallic output, about 5000 oz. of silver has been mined at Sullivan and Byard Point. The total value of the metal product of Maine to date, except iron, is probably about $400,000.

The Black Hills of South Dakota—VI

By William H. Storms

Besides gold, the Algonkian rocks in the Black Hills contain ores of copper, silver, lead, and antimony, and at several localities, large masses of pyrite. In addition to these, the granite dikes both of the Harney Peak region, and in the Nigger Hill district, contain tin, and in the former locality mica, wolframite, and spodumene in commercial quantity. Copper is found in a number of localities that have been slightly developed, and is known to occur also

In the Central Black Hills.

where little work has been done. Among the latter are the Blue Lead, near Sheridan, in Pennington county; an occurrence on the upper south fork of Rapid creek, 8 miles above Rochford; on the summit of a high hill, a mile north of Reynolds' ranch, near the south fork of Castle creek; at Hat Mountain, 2 miles south of Deerfield; at several places near the head of the north and middle forks of Box Elder creek, southeast of Bulldog ranch; on City creek, and on Deadwood gulch, near Deadwood; and in a few other localities of less importance. In each of these instances the copper occurs chiefly as malachite, azurite, and black oxide, in graphitic schists. These are the oxidation products of cupriferous pyrite in the schists and adjacent rocks. At several points a dense quartzite appears to be the chief original carrier of the sulphide, the oxide and carbonate ores occurring as impregnations in the soft schist next the quartzite. The large masses of pyrite in the Montezuma-Whizzers and other similar mines near Deadwood, are copper bearing to a small extent, but as development has extended to only a short distance below the drainage level, it is impossible to say what the normal copper content of this ore is at greater depths. It will probably be found to be higher than in the present workings, where the ore has, without doubt, been leached, as is indicated by the efflorescence of mineral salts on the walls.

Argentiferous galena occurs sparingly in the schist in a few localities, notably in the old Es-

Summit of Harney Peak.

condido mine near Galena. Galena was occasionally found in quartz on the north side of Deadwood gulch, opposite the Father de Smet mine, in 1878, where it was associated with visible gold. A small amount of galena was also found in the Uncle Sam mine (now the Clover Leaf), on Elk creek. On Whitewood, near Pluma, a thin seam of brittle-silver ore was discovered in early days, in what was known as the Beard mine, but the find was developed to only a limited extent. Antimony sulphide (stibnite) containing both silver and gold, occurs at Silver City, on Rapid creek, where it is scattered through large lenses of quartz in the schist, which in this locality is extremely hard and impregnated with finely disseminated pyrite. In the early history of the prin-

cipal mine, the Diana, the owners drove an adit nearly 500 ft. across the hard, dense slates and schists to reach the vein which outcropped on the hill above. This procedure is not unusual, but in this instance had the miners gone around on the Rapid creek side they might have run directly in on the vein, and thus saved several months of hard work.

About Rochford, and in the region of the gold belt on Castle creek; at Keystone; also near Custer; in fact throughout the central Hills, auriferous mispickel is of common occurrence. Some of these ores are high grade, others are of nominal value, the range being from $4 or $5 to $3000 or over per ton of concentrated mispickel. Some of that on Laughing Water, near Custer, is of very high grade. Not all of these ores, however, are arsenical, for some of them are remarkably free and consist chiefly of quartz with disseminated gold, no sulphide mineral at all being present. Often the quartz is glassy and of a character that the prospector is prone to condemn at sight, but occasionally it is extremely rich in gold, and when a prospector is fortunate enough to run across rock of this character filled with gold it usually cures him of his prejudice.

The remarkable vein-like dikes and lenses of granite in the region of Harney peak are most interesting. The granite is of the pegmatite variety and generally of exceptionally coarse crystallization. Orthoclase, albite, and other feldspars, with white, bluish, and beautiful rose-colored quartz, make up the greater portion of the rock, but black tourmaline is also present, occurring in crystals from slender hexagonal needles to great three-sided prisms with curved and striated faces. This mineral is abundant in places and gives the rock mass a most striking appearance. In some of the granite masses both biotite and muscovite occur, the latter often in large 'books', as the crystals are called by the mica miners. A great deal of merchantable mica has been mined from these dikes, particularly in the vicinity of Custer. Besides the minerals mentioned, crystals of green beryl, a foot or more in length, are abundant in some localities, particularly southwest of Custer. Wolframite, columbite, and tantalite also occur in some places, while cassiterite and spodumene are found in commercial quantities. In addition to these there is present a variety of other minerals chiefly valuable to mineral collectors.

The Etta mine, near Keystone, is in the most remarkable of all these granitic instrusions. The orebody occurs in mica-schist in the form of an elipsoidal mass, with a rudely concentric structure. That is, the minerals are disposed in rings or layers. The intrusion is approximately 200 ft. long and 150 ft. wide. A mixture of huge blocks of bluish-white quartz and albite feldspar forms the centre of the mass. This is enclosed in an envelope of albite and mica, much of which forms the rock known as greisen. Cassiterite occurs in the greisen and also in the non-micaceous albite. Outside this is another layer of massive albite, throughout which are scattered crystals of spodumene of such huge proportions as to almost surpass belief. These are the largest crystals thus far discovered in the world. They are disposed in all directions in the albite matrix, suggesting to the miner the timbers in a caved stope. In size they range from 1 to 4 ft. in diameter, and are from 10 to 50 ft. in length. They are for the most part perfect hexagons. The albite surrounding these huge crystals contains cassiterite. Inclosing this wonderful layer of minerals is a zone composed largely of mixed muscovite and biotite. This layer contains little or no tin. The Etta mine is certainly a mineralogical treasure house. The line of demarcation between the granitic material and the mica-schist is sharply defined at this mine. In fact this is true at all of these granitic intrusions, no sign of contact metamorphism being observable. I have noticed near the Etta mine a coarse granite dike of large size in contact with a rather coarse sandstone of Algonkian age, in which little mica could be seen, and there was not the slightest sign of metamorphism such as might be expected under the conditions. In some of the granite dikes large vein-like masses of quartz occur and cassiterite is frequently seen inclosed in the solid mass of the quartz. Columbite also occasionally occurs in large masses—one weighing a ton was reported from the Bob Ingersoll mine several years ago. The tin stone occurs in most erratic manner. One instance came to my attention, near Hill City, where a fortunate miner had a splendid prospect in a hole about 10 ft. deep. He sold out for several thousand dollars. When the transfer was completed and the money paid over, he astonished the purchasers by advising them to sell out at an advance, if they could, but under no circumstances to attempt further development, at least not in that shaft. Upon being pressed for a reason, he gave it as his opinion that the vein would not 'go down.' They laughed at the idea and promptly put in another round of drill-holes and blasted the last of the tin-bearing rock out of the hole. A large amount of money has been expended in the development and equipment of the tin mines of the Black Hills, but up to the present time commercial success has not resulted from these operations, although the tin is in the rock and all agree that the metal is of superior quality.

Soon after the discovery of gold in Deadwood gulch, lead-silver ore was found on Bear Butte creek, in the upper Cambrian quartzite, and later in other strata, notably in the basal quartzite and in the intermediate arenaceous limestones of the Cambrian. Here a town was built, called Galena. The principal mines developed on these ores were the Sitting Bull, Richmond, Florence, Red Cloud, and the El Refugio. In the Cambrian formation between Deadwood and Galena, gold, silver, and lead ores occur at no less than five different geological horizons, all of which can be found on the divide east of Spruce gulch, where the most noted mines are the Belle Eldredge, Champion, and Lexington groups. In each of these the orebodies are associated with laccolithic sills or vertical dikes, and usually with both. Several mills, and at Galena a smelter, were built to treat these ores. In the aggregate the output from these mines is in excess of $1,000,000. In 1880 argentiferous lead-carbonate ore was found in the rugged region

east of the Spearfish canyon, near the mouth of Squaw creek, but it was not until 1881 that these discoveries attracted much attention. Early in July of that year several rich finds were made, and a stampede occurred which in three weeks' time resulted in building up a town of 3000 people, called West Virginia City, but now known as Carbonate. Vigorous prospecting was carried on that year and hundreds of locations made, of which the most important were the Iron Hill and some others in its vicinity, about a mile south of the town, but it was not until 1885, when a mill and smelter were built, that the district became prosperous. The Iron Hill mine was the principal producer, and the output up to 1892 was nearly $700,000. The orebodies occurred in the Carboniferous limestones, though some ore, principally gold, was also found in the underlying Cambrian strata.

In the country around Terry peak, on Bald and Green mountains, and on various ridges of that region, and extending northward toward Carbonate and southward as far as Custer peak, is a mineral zone second only in importance to the auriferous belt in the vicinity of the famous Homestake. The ores of this mineral zone are valuable chiefly for the gold they produce, though silver also occurs. Sometimes it is in excess of the gold, as is the case at one shaft of the Portland group, where chloride of silver was found disseminated in a snow-white quartzite to the extent of 2000 oz. per ton. This was, of course, of limited occurrence. Throughout this region ores occur as a replacement in the basal quartzite of the Cambrian; in an impure limestone just above it, and in a second bed of limestone near the top of the Cambrian. Between these horizons are several others in which small amounts of ore have been found. Above all of these is another horizon marked by important ore occurrences, in the Carboniferous limestone, where is found surprisingly rich gold ore. The principal district in which the latter ore has been discovered is on the high limestone plateau near the butte known as Ragged Top, three miles northwest of Terry peak. The discovery was made in 1896 by prospectors who were not 'well posted', and who had the hardihood to have assays made of boulders of flint lying on the surface of the limestone, and which had been run over by scores of prospectors and scorned by them, myself among the number. This flint was rich in gold, was, in fact, shipping ore. News of the discovery started another stampede which quickly called three more new towns into existence—Preston, Balmoral, and Ragged Top. The flint which constituted the ore in these mines consisted of silicified fragments of a brecciated limestone, which had been crushed along the line of fractures in the rock. In 1881 flint was discovered in limestone in the Pocohontas mine on Squaw creek, which showed gold abundantly scattered through the rock and which was worth $4000 per ton.

Granite Needles Near Harney Peak.

The ores of the Cambrian formations were for the most part refractory and large fortunes were spent by the various mining companies before success was reached. The first attempts to treat the ores were by simple amalgamation, but it at once became evident that the ore could not be successfully treated in that manner, at least, not by the stamp-mill alone. The schools for experiment were the Portland and the Welcome mines, though some others made serious and expensive efforts in the same direction. At the Portland the 20-stamp mill was dismantled and pulverizers set up. These doing little if any better, and the expense being somewhat increased by their operation, the pulverizers were consigned to the dump and the stamps replaced. Then grinding pans were added, and by this means the extremely hard ore could be reduced to a fine pulp. A somewhat higher extraction was then obtained, but the cost was increased by the large amount of power required to operate the pans. About this time, 1884, a new type of pulverizer made its appearance. It consisted essentially of a double set of Cornish rolls operating within a cylindrical screen. The idea seemed feasible, but the rock was not broken fine enough for the pulverizer and it, too, was pronounced a failure. Had the ore been crushed with stamps and fed to the pulverizer better results would, no doubt, have been secured, but even if the ore had been reduced to a suitable fineness at not too great an expense, there would still have remained much to do before attaining a satisfactory solution of the metallurgical problem. In 1885-6, O. P. Ankeny built a mill at the Buxton mine, in Nevada gulch, in which he attempted to treat the telluride ores with bromine. He secured a good, or at least an encouraging, result, and there is little doubt that had he persisted in his experiments he would have been the first to successfully treat the ore. In 1890 the first chlorination plant was built at Deadwood, to treat the ore from the Cambrian formation—called locally 'silicious' ore. After running a short time the works burned, and a second and larger plant was built for the Golden Reward Co. This was a success. Barrel-chlorination was the process employed, and this mill, under the competent direction of several skilled metallurgists, did much to call attention to the great value and extent of the silicious ore deposits in the northern Black Hills.

Calculation of a Silver-Lead Blast-Furnace Charge

By James A. Barr

*Conditions.—Assume that it is desired to smelt as much dry siliceous ore as is possible with only enough lead for a collector and that zinc sulphide is present in the lead ore to an extent which would lead to choice of a slag of the C type, which is especially adapted to working zinc ores and at the same time is as siliceous as possible. It will be necessary to put enough roasted matte in the charge so that this product will not accumulate. Clippings, foul slag, etc., will have to be introduced after the plant is running regularly. The charge may be started with 50 lb. roasted matte, figuring the whole charge on the basis of 1000-lb. units for convenience. For the first, or starting charge the most favorable slag possible would be chosen so that the irregularities of starting may be more easily overcome. The analyses of ore, etc., are given on the accompanying charge sheet.

The next consideration is to get a safe amount of lead on the charge, assumed at 10%. This may be done by adding enough galena to furnish 100 lb. of lead or 167 lb. galena. Next, purely by guess and later by experience, 275 lb. siliceous ore is put in as the probable amount required to make a charge of 1000 lb. The next step is to figure out the weights of the various constituents SiO_2, CaO, etc. The total weight of the SiO_2 from the galena, matte, and siliceous ore, amounts to about 220 lb. This gives data enough to make the first estimate of the amounts of limestone and iron ore required.

Factors.—The Fe in the slag is $\frac{26.4}{34.0}$ or 0.78 times the silica. Knowing the pounds of silica going into the slag, the amount of iron required to go with it to make a slag of the given analysis, can be found by multiplying the weight of the silica in the charge by 0.78. $220 \times 0.78 = 172$ lb. Fe required or $172 \div 0.60 = 287$ lb. of iron ore since the latter only contains 60% iron. Since the matte will require iron and both the iron ore and limestone contain silica which is not included in the above amount of 220 lb., a slightly larger quantity of iron ore, 325 lb. must be taken.† $220 \times 0.5 = 110$ lb. CaO or $110 \div 0.54 = 200$ lb. of limestone or, allowing for the extra silica, about 225 lb. would be required. The analysis of the coke ash must be converted into terms of coke. The coke has 10% ash. The ash contains 75% silica; then the coke will contain 10% of the 75 or 7.5 silica. Complete finding the weights of the constituents and add up the total amounts.

All the iron is not available for the slags as some of it goes into the matte. The weight of the matte must first be computed from the amount of sulphur available. The slag contains 0.8% sulphur. Since the silica is 34% of the slag the weight will be $267 \div 0.34 = 785$ lb. and will contain 785 times $0.008 =$ 6 lb. of sulphur. Then allowing for 20% volatilization 20% of $23 = 5$ lb. of sulphur may be calculated, making a total loss of 11 lb. and leaving, $23 - 11 =$ 12 lb. of sulphur available for the matte. This amount will make $12 \div 0.20 = 60$ lb. matte containing 20% sulphur. To find the iron in the matte the copper must first be determined. Practically all the copper goes into the matte if sufficient sulphur has been provided. There is then 8 lb. of copper in 59.5 lb. of matte or $(8 \div 60) \times 100 = 13\%$ copper. Then the per cent of iron is $60 - 12.9 = 47.1\%$ Fe. The weight of the iron going into the matte will be 47% of 60 lb. or 28 lb. which must be subtracted from the total iron in the charge, leaving the iron available for the slag. If there were any arsenic present to form a speiss, 2.3 of its weight must be subtracted from the total iron. The next step is to see if the iron and calcium oxides are present in the right amounts to form the slag given. (Computation C.) According to the factors the Fe is 0.78 times SiO_2. There is 267 lb. of SiO_2 present, hence there should be 0.78 times $267 = 209$ lb. of iron present, but only 206 lb. is available, hence there is a deficiency of 3 lb. or in terms of iron ore, $3 \div 0.60 = 5$ lb. The charge will have to be corrected by adding this amount and if the error is very large all the computations will have to be gone over. According to the factor the CaO is 0.5 times the SiO_2, hence 267 times $0.5 = 134$ lb. CaO is needed. There is 139 lb. CaO on the charge which is an excess of 5 lb. CaO or $5 \div 0.50 = 10$ lb. of limestone which is added to the charge.

If desirable the approximate amount of base bullion may next be calculated, by subtracting the weight of the lead in the matte and slag from the total weight in the charge. This, of course, does not account for other metallurgical losses which are offset in a measure by the impurities entering the bullion. Lead in the matte may be determined as follows: 60 lb. of matte assaying 15% lead would contain 60 times $0.15 = 9$ lb. of lead. That in the slag may be found as follows: 785 lb. of slag assaying 0.8% would contain 785 times $0.008 = 6$ lb. lead. Total $9 + 6 = 15$ lb. of lead or $107 - 15 = 92$ lb. base bullion.

Knowing the weight of the base bullion its probable assay may next be computed. First compute the total weight of the gold and silver in the ores (not including the matte) from the assay values (Computation E), subtract from these amounts the weights going into the slag and the result will be the amounts going into the base bullion, not taking into account the other metallurgical losses such as volatilization and flue dust. The reason the matte is

*Abstract from 'Testing for Metallurgical Processes.'

†The amount of iron in the incoming matte is 25 pounds.

not taken into account is that, while silver and gold are introduced into the charge by the roasted matte, practically the same amounts will be taken out by the matte that is formed. Where matte is fed irregularly this short cut cannot be taken.

SLAG	Per cent.

ASSAY OF BASE BULLION

$\frac{2000 \times 3.928}{92} = 81.0$ oz. Ag per ton.

$\frac{2000 \times 0.137}{92} = 2.98$ oz. per ton Au.

Revised Atomic Weights

By F. H. Mason

In compliance with a general request, that the result of its investigations may be made known at the commencement of the academic instead of the calendar year, the International Committee on Atomic Weights has issued its report some three months in advance of the usual date. The object, as will be evident, is to facilitate the duties of both teachers and students, by preventing changes after the work of the term has begun. The committee has investigated researches that have been made on the atomic weights of chlorine, lithium, platinum, phosphorus, rhodium, silver, strontium, tellurium, vanadium, and the group of inert gases. Changes, however, and these but slight, have been recommended only in the cases of argon, helium, krypton, lithium, neon, phosphorus, platinum, strontium, vanadium, and xenon. The change in the atomic weight of lithium is recommended from the research of Richards and Willard (*Jour.* Amer. Chem. Soc. 1910, 32, 4), who measured three distinct ratios, silver to lithium chloride, silver chloride to lithium chloride, and lithium perchlorate to lithium chloride. From these ratios they obtained the following values, lithium = 6.939, chlorine = 35.454, and silver = 107.571, as against the old figures, lithium = 7.00, chlorine = 35.46, and silver = 107.88. The committee, though stating that the new figures are entitled to great weight, in view of the excellent work done by other experimenters—notably Gray and Burt—deems it unwise in the case of chlorine and silver to make any hasty change, but in the case of lithium has adopted the figure obtained by Richards and Willard, rounded off to 6.94. In determining the atomic weight of strontium, Thorpe and Francis (Proc. Roy. Soc. 1910, 83A, 277) measured six ratios, silver to strontium bromide, silver bromide to strontium bromide, silver to strontium chloride, silver chloride to strontium chloride, strontium bromide to strontium sulphate, and strontium chloride to strontium sulphate, and obtained, as a mean, the figure 87.646 as the atomic weight of strontium. This closely agrees with the figure obtained in a recent research by Richards, 87.62, and the committee has adopted the intermediate figure 87.63. Baxter and Jones (*Jour.* Amer. Chem. Soc. 1910, 32, 298) measured the ratio of silver to silver triphosphate, and obtained for the atomic weight of phosphorus the figure 31.043. The rounded-off figure 31.04 has been adopted. The committee has provisionally adopted the figure 51.06 as the atomic weight of vanadium from researches by Prandtl and Bleyer (*Zeitsch.* Anorg. Chem. 1910, 65, 152, and 67, 257) on the ratio of silver chloride to vanadyle trichloride and on the analysis of vanadyle trichloride. In an elaborate investigation (*Proc.* Roy. Soc. Edin. 1909, 29, 721) on the composition of chloro and bromo platinates of potassium and ammonium, Archibald obtained, as an arithmetical mean of twenty-eight ratios, the figure 195.22 for the atomic weight of platinum. The figure 195.20 has been

adopted. The atomic weights of helium, neon, krypton, and xenon have been redetermined by Watson (*Trans.* Chem. Soc. 1910, 97, 810, and 97, 833), while Fischer and Hehnel (*Ber.* 1910, 43, 1435) have redetermined the atomic weight of argon.

The new atomic weights, then, that go into force at once, are: argon, 39.88; helium, 3.99; krypton, 82.90; lithium, 6.94; neon, 20.20; phosphorus, 31.04; platinum, 195.20; strontium, 87.63; vanadium, 51.06 (provisional); xenon, 130.20.

It is pleasing to note, in going over these reports each year, that Americans are coming more and more to the front in the accurate research work of determining the atomic weights of the elements, the foundation stone upon which analytical chemistry rests.

REQUISITES FOR AIR-HAMMER DRILL BITS

By G. E. Wolcott

In spite of all that has been written upon the proper shape of drill bits for different machines and different conditions, there is still considerable ignorance or misunderstanding of the proper requisites for a drill bit. Of first importance, in considering the matter, is the distinction between two types of stoping bars and the effect they have upon the behavior of the drill bit and upon the cutting capacity of the drill. There is, first, that class of machines in which the air goes through the stoping bar before going to the piston. By this arrangement a slight vibration up and down is produced and the bit partakes of this motion. This style of stoping-bar is exemplified in most of the older machines, such as the Murphy, Hardsoeg, Shaw, and Eclipse. Second, there is that class in which the machine is held up by a constant air pressure, as in the Waugh and Cleveland. In these machines the bit is held firmly against the rock with little vibration. The difference in effect of these arrangements is reflected in the cutting capacity of the machine and the difficulty of turning the bit in the hole. The first style gives a machine that will turn easily, but has a lower drilling capacity, while the second gives a machine that will turn with difficulty but has a higher cutting capacity for the same air consumption. It is evident, therefore, that the second arrangement is the more economical if the drill bit can be so shaped as to overcome the difficulty incident to turning it in the hole. A machine has often been condemned where a proper understanding of this point would have overcome the difficulty. Fig. 1 shows the construction of a bit which has been made to overcome the objection of difficult turning and which has been widely adopted for air-hammer machines. The dimensions given are such as would ordinarily be used for a starter bit where 1⅛-in. ribbed steel is used. The object of the high centre is briefly this. When starting a hole with a square bit it is always found that there is a tendency, more or less pronounced, according to the nature of the rock and the shape of the face, for the bit to rotate about one corner of the steel rather than about the centre. The result is either a broken corner or difficulty in getting the hole started, or both. With the high centre, the latter strikes the rock first and rotation about the centre is easily effected. The result is that no difficulty or loss of time is experienced in starting a hole. Another advantage is that the drill stays sharp longer than with a square bit. The tendency in any bit is for the outer corners, which have the most cutting to do, to wear away or become blunt first. With the high centre the cutting is more equally distributed. In the illustration the angle between the faces of cutting edge has been shown as 90°. The exact angle is not material, but it is of the utmost importance that it should not be acute. It is natural to imagine that a sharp bit means fast cutting, but the reverse of this is frequently the case, especially with the second type

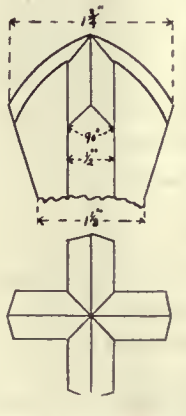

Fig. 1. Bit for Hammer Drill.

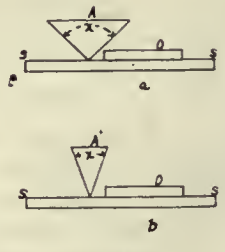

Fig. 2.

of stoping-bars mentioned. In Fig. 2 is illustrated the reason for this. In *a* has been represented by the wedge *A* the conditions which exist on a bit with a 90° angle, and in *b*, conditions with a bit having an acute angle. Suppose these wedges to be drawn along the smooth surface *ss* and to meet the obstruction *o*. The difficulty in passing over the obstruction will be proportional to the angle *x*. The result is that with a sharp bit either the obstruction must be broken off by the force exerted in turning the drill, or the point of the bit will be broken. In this case the operator, rather than the machine, does the work of breaking the rock. With a slight interruption in the turning, the difficulty at once increases as the hammer is continually striking and the relative height of the obstruction constantly increases until it is impossible to turn the bit. Another reason for the blunt edge is that a hard temper may be given it without danger of breakage, and in drilling hard ground this is a prime requisite. Often the importance of having proper steel with proper bits is not fully realized and too little attention is given to this point. The result is that in many cases hundreds of dollars are lost every month in wages paid to men who are doing nothing but waiting for steel or trying to perform work with such tools as render it impossible to accomplish good results.

Mount Lyell mine in Tasmania is one of the largest low-grade copper mines in the world. Smelting is accomplished there at a surprisingly low cost. The ores are wholly sulphide. Mining is done with steam shovels. A heavy overburden has to be stripped before the ore beneath is available.

The Work of the Tennessee Copper Company

By Karl R. Morgan

The Tennessee Copper Co. operates three mines, the Bura-Bura, the London, and the Polk County. In all of these the character of the ore and methods of mining are the same. The Bura-Bura, which is the largest mine and producer, is the one described herein, though mention is made of the others. The first discoveries were made in the Ducktown district about 1850. Operations were at first confined to the working of rich oxidized ores near the surface. Upon the exhaustion of these, attempts were made to treat the low-grade sulphides, but this proved unsuccessful and work was abandoned about 1878. In 1897, the exploration and development of the Bura-Bura and the London mines were undertaken by diamond drilling, and as the results proved favorable, the Tennessee Copper Co. was organized. This company bought later the Polk County mine and started development in 1899. Construction of the railroad, roast yards, and smelters soon followed.

The practice of heap roasting preliminary to smelting in blast-furnaces was at first employed, the matte so produced being blown to blister copper in converters. This continued until 1904, when the present process of 'raw sulphide' or 'pyritic' smelting was introduced. The process as employed at Ducktown is today the best example of straight pyritic smelting to be found in the United States.

The rocks in the Ducktown district consist mainly of gneiss and mica schists. Folding and faulting is thought to have occurred and the ore deposit is found along fault fissures. The strike of the strata is northeast, while the dip is southeast at an angle of about 75 degrees.

The ores occur in semi-detached lenticular deposits, the longer horizontal axis of the lenses running parallel with the strike of the country rock, and dipping in the same direction but at a slightly steeper angle. The detachment is thought to be due to cross-cutting fault lines at acute angles, resulting in horizontal throws of 30 to 60 ft. The average width of the orebodies is 50 ft., the maximum 180. The veins show clean-cut foot-walls. The hanging wall is poorly defined and the limit in that direction is an economic one. Mining is continued in the direction of the hanging wall until the ore becomes too poor to mine. The mines are comparatively dry, one small pump, running six hours per day, handling all mine water.

The ore consists largely of pyrrhotite with chalcopyrite and iron pyrite; blende and galena are also present in small amounts. The chalcopyrite contains the copper, which amounts to about 2%. Because of the large amounts of pyrrhotite and pyrite, the iron content is high, 30 to 40%. In the gangue are found garnet, zoisite, horn-blende, pyroxene, calcite, and quartz. Mica occurs on the hanging-wall side. Zoisite occurs chiefly in the Polk County mine.

COMPOSITION OF ORES

	Bura-Bura, per cent.	London, per cent.	Polk County, per cent.
Fe	38 to 40	26 to 28	32
S	30	16 to 18	20 to 22
*Insol	15	44	34
Cu	2	2	2
Zn	1	—1	1.5
CaO	6 to 8	6 to 7	6 to 7
Al_2O_3		3	3 to 4
MgO		2	3

*Including: in Bura-Bura ore, SiO_2, 12%, silicates, 3; in London, SiO_2, 38 to 40, silicates, 4 to 6; in Polk County, SiO_2, 28 to 30, silicates, 4 to 6.

Methods of mining employed are similar in all the mines, and are best shown at the Bura-Bura. The main shaft is sunk in the foot-wall rock at some distance from the orebody; at the Bura-Bura this distance is one hundred feet, and the shaft has an inclination of 75°. Levels are opened every hundred feet; the first level at the Bura-Bura being 172 ft. from collar of shaft. Six levels are in operation here and the shaft is sunk to the eighth. The ore extends, no doubt, to still greater depths. Cross-cuts to the ore are driven on each level and connections between levels made opposite the shaft by raises. Stopes are started in both directions on the vein, resulting in two stopes the full width of the body and 70 ft. high, leaving a pillar 30 ft. thick between levels. In addition pillars are left wherever it is considered necessary. These pillars are comparatively few in number, but make timbering largely unnecessary. Eventually all pillars and floors will be robbed. The ore is shot down from the working face and at the foot of the stopes is shoveled into cars holding 2½ tons. It is trammed to the shaft, dumped into 5-ton skips, and hoisted to the surface. Exploration is carried out by means of drifts driven on every third level, in which, at every 100-ft. station, holes are bored with diamond-drills in both the hanging and foot-walls, and the width of ore determined. Development is now under way at the old McPherson shaft, which has been cleaned out and sunk to the third level, at which point it can be connected with the corresponding level of the Bura-Bura. The connecting drift will be slightly over a quarter of a mile long. All drilling is done with 3¼-in. Rand drills. All labor in the mine is done by contract. A drill-runner is paid 15c. per foot and he pays his helper $1.75 per day. Thirty feet is drilled per day on the average, and a good man can make forty. The record is 1000 ft. in one month. The ground is hard. Trammers are paid 28c. per car. Blockers receive $1.90 per day and shoot their own holes; all other holes are shot by the powder gang.

At the surface the ore is dumped into a receiving bin from which it is fed into an 18 by 36-in. Blake crusher, from which it is carried by means of a conveyor belt to storage bins of 2000 tons capacity. While on the belt all barren rock is removed as far as possible by hand picking. From storage bins the ore is drawn into cars and hauled over the company's railroad to the smelter, a distance of about seven and a half miles. Track is standard gauge, 65-lb. rail being used.

The surface plant of the Bura-Bura mine consists

of a wooden shaft and crusher house 125 ft. high, brick power and boiler houses, together with various wooden buildings as office, shops, and change rooms. The power-house contains a Nordberg first-motion hoisting engine with 18 by 32-in. cylinders, with two conical drums 7 ft. diam. at the small end, 9 at the large, and with a 5-ft. face. Air is furnished to the drills at 80-lb. pressure from Nordberg two-stage compressors. The air cylinders are 15 by 24 by 42 in.; the steam cylinders are 14 by 28 by 42 in. The capacity of these compressors is 2000 cu. ft. of free air per minute. The boiler plant consists of four 150-hp. Babcock & Wilcox water-tube boilers, equipped with Murphy automatic stokers. A small dynamo furnishes light.

At the London mine there is a shaft similar to that of the Bura-Bura. It has a depth of 562 ft., and five levels are open. The Polk County mine is opened by a vertical shaft sunk to the depth of 385 ft. where the fourth level is opened. Three levels are in operation. The production from these shafts is Bura-Bura, 1100 tons per day; London, 250; Polk County, 250.

At the smelter the ore is dumped into bins of 10,000 tons capacity, which are divided into compartments of 250 tons. Each of these is provided with a chute controlled by a gate through which the ore is drawn into small side-dumping charging cars, in which it is drawn to the furnaces by electric locomotives. The cars have a capacity of 44 cu. ft. Four tracks run under the bins, provided with scales for weighing the charges. Tracks are arranged so that cars loaded at any bin may be dumped into either side of any furnace.

There are 7 blast-furnaces, 4 being 56 by 270 in., and 3, 56 by 180 in. at the tuyeres. The height from the tuyeres to the charging floor is 18 ft. From tuyeres to sole plate is 3½ ft. Sole plates are of cast iron and are water-cooled. The small furnaces have twenty-six 5-in. tuyeres, and the larger ones fifty 3¼-in. tuyeres, arranged in pairs, one pair to each section. On one of the larger furnaces the space between each pair of tuyeres has been cut out, making the tuyere opening a slot 4 by 12 in. The results obtained are good, pressure being reduced and capacity increased, though more air is required. Air is furnished to the furnace under 50-oz. pressure. The blast is cold. Each furnace consumes 70,000 to 90,000 cu. ft. of air per ton of ore smelted, or about 1000 cu. ft. of air per minute per foot of length. Each furnace is provided with a circular settler 16 ft. diam. and lined with fire brick. In these the furnace products are allowed to separate, the slag overflowing through a slag tap into pots of 105 cu. ft. capacity, in which it is hauled to the dump. The low-grade matte is tapped from a lower level at intervals into pots similar to those used for the slag. The matte from the green-ore furnaces goes to cooling beds; that from the concentrating furnaces to the converter. The converter slag is also poured into these settlers and allowed to settle, no attempt being made to re-smelt this slag. This is new, converter slag generally being re-smelted. The shells of slag formed in the ladle by cooling form the only part of the converter slag re-smelted at this plant.

There are fifteen converters of the Leghorn type, 7 by 12½ ft. in size and four electrically operated stands. Two 40-ton electric cranes handle matte from furnaces to converters. Converters are lined with a mixture of clay from Georgia and ground quartz-ragging from the quarry at Astral, this being crushed to ⅜ in. The materials are mixed in a pug-mill. From it the mixture is hauled to converters undergoing repair, shoveled into them and tamped about a core. Air hammers or tampers are employed. Linings last two charges or blowings.

The furnace gases, consisting chiefly of SO_2, SO_3, CO_2, O, and N, together with the flue dust, are discharged either wholly or in part into a brick-lined balloon flue or a concrete flue below the furnaces, as desired. Both flues discharge into a dust chamber 209 by 30 by 20 ft., at the end of which is a radial stack of pressed brick 325 ft. high. The flue dust is removed from the chamber by two 12-in. conveyors. At the time of my visit no attempt had been made to briquette and re-treat the dust. A briquetting plant was soon to be erected. White presses were to be used. The flue dust formed and collected amounts to 1½% of the charge.

Smelting is carried on in two stages, 80% of the total sulphur content being eliminated. The remainder is expelled in the converters. In the first stage green ore is fed with coke to the furnace, but no fluxes other than quartz. A low-grade matte carrying 13 to 15% copper is produced. The slag is dumped, and the matte is hauled to the cooling beds, dumped and allowed to cool, then broken up and hauled to bins. In the second stage the matte from these bins is fed to the concentration furnaces with quartz, coke, and limestone. The slag formed is dumped and the matte, which now carries between 30 and 40% copper, is sent to the converters and blown to copper 99.4% fine. The converter slag is run back to the furnace settlers while the copper is cast into pigs weighing about 225 lb. in which form it is ready for the market.

A matte carrying 30 to 40% copper could be obtained upon first smelting if desired, but it was found better to carry the process on in two stages as outlined, because the loss in copper is greatly reduced, a better saving obtained, and profits increased. More ore is mined and smelted from the Bura-Bura

than the other mines. The result is a high per cent of iron present, which must be fluxed as a silicate by the addition of quartz. The amount of iron present always influences the amount of quartz necessary, which requires, and is accorded, the closest attention. The quartz used is obtained at Astral, Tenn., and contains 96 to 98% silica. Formerly it had been obtained in North Carolina, but the cost was high, so the company bought its present holdings, from which it procures all quartz necessary.

A West Virginia coke with a 12% ash is used. The total used in the two smelting operations is about 6 to 7% of the total weight of ore smelted.

Limestone is added in the second or concentrating stage of the process. This is a new practice at the plant. Formerly the iron was slagged as a straight iron silicate; now, by replacing part of the iron with calcium, an iron-calcium silicate is produced. A lighter slag results and a much better separation of slag and matte is obtained in the settlers. The limestone is from the Georgia marble quarries.

Water for jacket and general use about the plant is pumped from the Ocoee river by two motor-driven, 10-in. turbine pumps having a capacity of 2800 gallons per minute. The jacket water is run by means of a flume or race to a pond below the smelter, where it is cooled and pumped back into a second and lower series of tanks, where it is again ready for use in the furnaces. About 7% of heat is lost in the process.

All copper determinations are made by the electrolytic method. A one-sixth horse-power alternating-current motor furnishes the power. Series devices are used on a direct current where high-current densities are employed with lamp rheostats. An interesting feature of the practice is the use of rotating anodes, with which a complete analysis can be made in from 20 to 30 minutes.

The latest development is the erection and operation of a sulphuric-acid plant. Construction began early in 1906, and acid-making commenced on December 1, 1907. Owing to the changes necessary to be made to the tops of the green-ore furnaces which furnish the gas, full capacity had not been reached at the time of my first visit. Then but two furnaces were feeding the plant. From the gases supplied 400 tons of commercial 60° H_2SO_4 was manufactured daily. This was to be increased to 800 tons when the other two furnaces were put in commission. This will place the Tennessee Copper Co. at the head of the sulphuric acid industry and will do much to reduce the cost of both the commercial and refined acid in the United States.

The essential features of the plant are the same as in the ordinary sulphuric-acid plant. The chief difference is the source of the gas supply, which is in this case the gas from the green-ore blast-furnaces. The acid plant consists of 2 Glover towers; 12 lead chambers, 50 by 50 by 70 ft.; 4 Gay-Lussac towers; 10 storage tanks, 700 tons each.

Only the fumes rich in SO_2 (those from the green-ore furnaces carry over 6% of this gas) are used in the manufacture of the acid. These fumes carry not only SO_2, but SO_3, CO_2, O, and N as well. These gases are drawn from the furnaces to the concrete flue back of and below them. From this flue the fumes are taken into the Glover towers. Here the sulphur content is converted to SO_3 by addition of nitrous oxides obtained from a solution of $NaNO_3$ in dilute H_2SO_4. The gases then pass to the lead chambers, which they enter at a point near the top. Here they are met with a jet of steam, the following reaction taking place:

$$SO_3 + H_2O = H_2SO_4.$$

The H_2SO_4 precipitates to the bottom of the chambers while the spent gases pass to the Gay-Lussac towers where the nitrous oxides are recovered by dissolving them in H_2SO_4. The remaining gases then pass from the Gay-Lussac towers through the flue leading to the stack, and thence to the atmosphere. The acid in the chambers has a specific gravity of about 1.58. This is sampled and tested from time to time by means of taps in floor of the chambers. From the chambers the dilute acid is sent back to the Glover towers, where it is concentrated to a specific gravity of about 1.75, after which it is passed to the storage-tank preparatory to loading into lead-lined tank-cars. These cars have a capacity of about 55 tons each and in them the acid is marketed.

The works of the company are under excellent supervision and are notable for the large amount of experimental work that has been carried out in them. The results have amply justified the liberal policy that has been adopted.

VANADIUM STEELS

The following, from a pamphlet issued by the Vanadium Steel Company of Pittsburg, is of interest, as it describes the effects of vanadium when added to steel. Vanadium exerts its power in at least three ways.

1. It indirectly toughens steel owing to its powerful scavenging action, removing oxides, nitrides, etc., in a fusible form easily carried away to the slag. In this respect it differs markedly from some other deoxidizing alloys.

2. It directly toughens steel mainly by its solid solution, under normal conditions, in the carbonless portion known as ferrite. To succeed in this respect, the allow must contain either free vanadium, or vanadium combined with some other element which also goes into solid solution in ferrite under normal conditions, such as silicon.

3. It forms complex carbides of such natures as to statically greatly strengthen the steel containing them. These carbides are proved to add more strength to steel when they contain chromium or nickel.

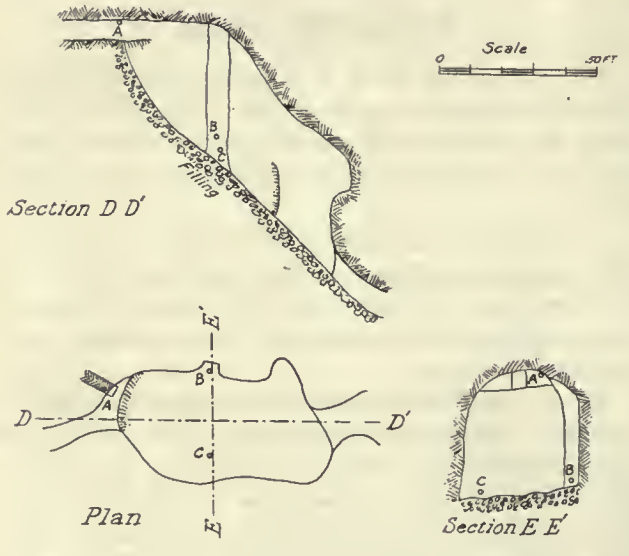
There is no one type of vanadium steel that does all things. It is necessary to make various kinds and grades for different purposes to which different vanadium steels have been successfully applied.

In the tables presented, with regard to composition and heat-treatment, the results have been mainly deduced from experience with basic open-hearth chrome-vanadium steels, and are corroborated by service records and by exhaustive microscopic investigation.

Surveying an Inaccessible Stope

By A. E. Robinson

A mining company, working its mine by the process of breaking and sorting the ore in stopes, and filling with waste, had drawn a large quantity of filling from an abandoned stope. This stope was in rock sufficiently firm to support the sides and back without caving. I was directed to survey this stope and to determine the position of the boundary walls with as great accuracy as possible, as it was desired to make a model of the workings. The accompanying sketch shows the general outline of the stope, no attempt being made to indicate details. Owing to the fact that the back of the stope was about 45 ft. above the filling that had been left in it, none of the ordinary methods of surveying was applicable. To complicate the problem, there were few places where a transit could be set up, and the walls being nearly vertical, the only contour that could be reached was one about 8 ft. above the filling. It was not possible, nor practicable, to attempt to use ladders, and extreme care had to be exercised not to start a movement of the filling, which rose abruptly just below the intermediate level shown at the top of the stope, and where it was necessary to station a transitman.



Obviously the best method was that of triangulation, but the difficulty of using this method lay in getting points on the walls. After experimenting with little success with different lights and reflectors, in the hope of finding one that would cast a single concentrated beam of small diameter to a distance equal to the maximum distance of any point on the wall from the transits, I acted on a suggestion of Rush J. White and tried passing a ray of light through a camera lens. I found that by removing the ground glass from a 4 by 5 camera fitted with a Gundlach telephoto lens, and placing a Baldwin acetylene mine lamp in the back of the camera, it was possible to project a small beam of light of sufficient brilliancy to illuminate a circle about 0.10 ft. diameter at a distance of 10 ft. from the camera. The diameter of this circle increased in direct proportion to the distance, and was visible through the telescope of a transit as far as 60 ft. A stronger light, had one been available, would have been desirable, for the reason that at distances of 30 ft. and over, there was some difficulty in bisecting the circle of light with the crosshairs.

Three transits were used; one at the point marked A on the map, where the intermediate level joined the stope, and the others at B and C. The setup at A was particularly dangerous owing to the liability of the filling starting to cave. B and C were used for points, not so much because they were desirable, although a fairly good view of the stope could be had from both, but because they were practically the only places left where a transit could be set up and not slide out of position when the transitman moved. No transit points were set at these places, as it was impossible, but the line was carried to a known position in the lower portion of the stope. The transitman at A entered through the intermediate level. When a sight was to be taken, all the lights except the camera light were extinguished, a spot on the wall was chosen, the light projected on it, and the two transitmen who could get the best view would sight to it. The vertical angle at each transit was read for a check. The greatest distance a point was sighted was about 45 ft.; all elevations checked within 0.30 ft., proving the work to be accurate, not only for elevations, but for positions of the points as well, within reasonable limits.

Loss in Weight Due to Roasting.—When an ore is assumed to be roasted, as must often be done in preliminary calculations, it is necessary to approximate its analysis without resort to actual trial. Since oxygen (16) is one-half the atomic weight of sulphur (32), in roasting from sulphides to oxides the loss in weight can be approximated as one-half the loss of sulphur. Example:

Analysis original ore.	Per cent in 100 lb. ore.
SiO_2	60 or 60 lb.
Fe	20 " 20 "
S	20 " 20 "
Total	100 in 100 lb.

Roasted to a product containing 5% sulphur: loss in weight $= 100 - \frac{20-5}{2} = 92\frac{1}{2}$ lb.; therefore in $92\frac{1}{2}$ lb. of roasted ore there is SiO_2 60 lb., Fe 20 lb.

The new approximated analysis would be:

	Per cent.
SiO_2 $\frac{60}{92.5} \times 100$	$= 65.0$
Fe $\frac{20}{92.5} \times 100$	$= 21.6$
S assumed	$= 5.0$

The following slag tables (by Hoffman) show the variation of constituents possible in the different silicate degrees with the attendant effect on the temperature formation. The metallurgist must not be entirely guided by the low formation points of the highly silicious bisilicates as they need a temperature considerably higher to flow properly. They may be used successfully in semi pyrite smelting on account of the high temperature attained.—Barr.

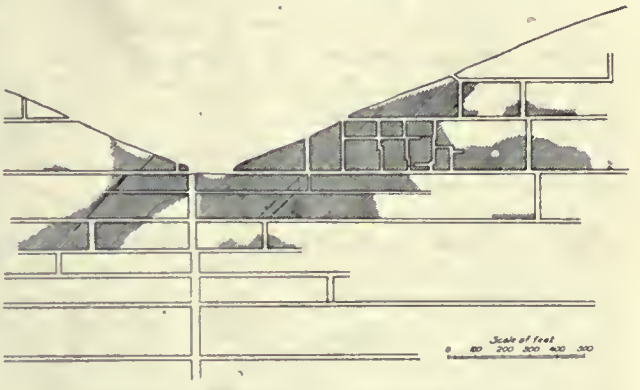
Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

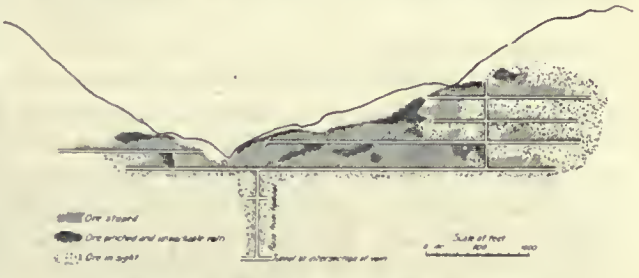
Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—I do not agree with W. H. Storms in his contention that it is rarely, if ever, that ore-shoots, or the value occurring in a vein, extend through that portion of the vein underlying a canyon, gulch, or natural depression which crosses the strike of the vein, and that it seemed a safe proposition to steer clear of mines situated in gulches so crossing the strike of the vein, or in a country cut by a succession of short ravines. The accompanying longitudinal sections are of the Eureka & Excelsior mine in the Sumpter district, Oregon, and of the Liberty Bell, at Telluride, Colorado, both of which have been previously published. Of the former I have personal knowledge, and without question Mr. Storms' theory does not hold good in this instance. The section of the Liberty Bell is from an official report, and seems to also negative Mr. Storms' theory. I could cite numerous cases in California mines, in Grass Valley, and other districts, where the ore-shoot continues unbroken and with no appreciable difference in value in that portion of the vein underlying one or more gulches. As these mines were studied while under professional engagements, I do not, at the present time, feel at liberty to go into detail concerning them. Unfortunately, I lack sufficient detailed data concerning those mines where I would feel no hesitancy in discussing Mr. Storms' theory, and to undertake to do so would be a matter of little interest or profit, but I may say that without exception wherever I have had occasion to note the conditions described by Mr. Storms of canyons or gulches crossing the vein in its strike, I can recall no instance where such depressions, unless formed near the contact of different rocks or along a fault plane, seemed to bear any relation to impoverishment of the ore-shoot underlying same, if there was any in the vein up to that point. I believe, on the contrary, that under certain conditions, secondary enrichment has proceeded to a limited extent in such places. The impoverishment or pinching of a vein passing into a different formation is of common occurrence whether the point of contact happen by chance to be under a gulch or not, and the erosion of the orebody, by the agencies forming the gulch or ravine, is, of course, frequent, but these, however, are not the points that Mr. Storms wished to make. I have noticed that certain surface conditions or indications at some mines apparently had some connection with the character of ore-shoots or vein occurrences directly below those points, and, in some instances, there has been a remarkable similarity of these conditions at different mines. I hope before long to be able to get my notes in shape on the subject. I think that an attempt to judge the value of a mine or prospect from the topographical features would be rather a dangerous policy, and a matter that would appeal more to the promoter than to the mining engineer, and to the former, of course, favorable to the property. While there is much of interest in Mr. Storms' article, and many statements made with which I agree, I must say that I do not approve of nor agree with his statement in paragraph 10, as follows: "There is no means by which the value of ore beneath the surface as yet undeveloped, may be even approximately determined, regardless of all signs at the surface, favorable or otherwise. Only actual development can make this condition known." If Mr. Storms means the above to apply only to the topographical features, it does not seem clearly stated, and if the intention is to imply that there is nothing to be determined from a study of the surface showing to justify the



Longitudinal Section Eureka & Excelsior Mine, Oregon.



Longitudinal Section Liberty Bell Mine, Colorado.

engineer forming an opinion of the values to be found in depth, then I believe Mr. Storms clearly in error. Extensive field experience has demonstrated that a careful study of the surface conditions and geology, and the taking of numerous samples that are truly representative (from open cuts, shallow pits, outcrops, etc.) give the engineer a basis for estimation that is actually indicative of the value that may be expected in depth. While there are numerous instances where ore of value has been found in depth where there was apparently no indication of it on the surface, still this, in my experience, is the exception, and not the rule; it is the favorite expression of one miner I know to declare that 'the values have gone to the deep,' which is undoubtedly the case, in his mind, when they cannot be found elsewhere.

CHARLES JANIN.

San Francisco, November 10.

Arsenical sulphide ores upon natural oxidation usually present a peculiar yellowish green color which is easily remembered. In some districts miners erroneously refer to this color as tellurium stain.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Borax glass when kept long in a moist climate tends to run together and must be re-crushed before being used. For this reason it is now supplied in tin-lined cases.

Mining locations should be laid out on the surface in such manner that the side lines parallel the outcrop, regardless of the true strike of the vein. A vein with considerable dip—45° more or less—will appear to have a very different strike on a sidehill crossing the vein than it actually has.

Average cost of mining and milling on the Mother Lode of California ranges from $2 to $4 per ton, depending on the magnitude of mining operations in both mine and mill. Surrounding economic conditions are also an important factor. A mine that can be operated through adits has an advantage in working cost over one operated through a shaft.

Time required in sinking shafts in the greenstone of the Mother Lode is usually divided about as follows: drilling with machines, 12 hr.; clearing away broken rock and squaring up, 8 to 9 hr.; handling men, timbers, supplies, and materials, setting up and taking down machines and clearing the bottom of the shaft from smoke and gas, 3 to 4 hours.

Ammonium cyanide is a more efficient solvent of gold for silicious gold ores containing a small amount of cyanicides, particularly copper carbonate, than potassium cyanide alone. It is said that a still better solvent for the gold in ore of this description is potassium cyanide to which has been added a small amount of ammonia. The quantity of ammonia required varies with the strength of the solution.

All pipes in mills in cold countries used for carrying water, solution, steam, or any liquid should be so placed that they may be completely drained by means of valves situated at the lowest point, so that in the event of the mill being closed down, even temporarily, these valves may be opened and the pipes cleared. This will prevent freezing, and possibly the splitting of the pipes by formation of ice.

Neither a millsite nor a placer claim can be entered by a stranger for the purpose of prospecting for a quartz vein or other mineral deposit, for the reason that he is a trespasser. The law pre-supposes that a millsite is non-mineral land, and no one has the right to assume that a quartz vein is hidden under the surface of the gravel of a placer claim. Even if it does occur the vein cannot be sought by the outsider.

The hardness of minerals is determined by comparison with minerals of known hardness. The scale adopted by standard mineralogists is: tale, 1; gypsum, 2; calcite, 3; fluorite, 4; apatite, 5; feldspar, 6; quartz, 7; topaz, 8; sapphire, 9; diamond, 10. Occasionally minerals differ somewhat from the arbitrary scale, different specimens of the same mineral varying a little in hardness. This property of minerals is sometimes deceptive, granular varieties appearing to be much softer than the crystallized specimens. Thus a friable quartzite may seem to be softer than a quartz crystal, when, in fact, the individual grains of the granular rock are as hard as the crystal.

The discoverer of a vein within the lines of an agricultural patent, if not the owner, may be able to locate the vein on its strike, outside of the agricultural patent and 'construct' a location on the vein the same as though no prior title existed. Such constructive location, however, does not give the mine locator any surface or underground rights within the lines of the agricultural patent. The miner may take his extra-lateral right, based on such discovery, from the surface downward on the dip of his vein along that portion lying without the patent, and he may also take the same right from a line along the vein beginning outside of and directly under the line of the agricultural patent. No vein within an agricultural patent is entitled to extra-lateral right.

Air compressors should be supplied with the coolest and purest air obtainable. For this reason the intake-pipe should be extended outside the compressor building. If there be a leak leading from the cylinder to the intake-pipe which permits some of the compressed and heated air to return to the intake, there is danger of the compressor becoming hot and either exploding the jacket or setting fire to any oil that may be present in either cylinder, receiver, or pipe. This burning oil would then be forced into the main line of the system and into the mine workings through the exhaust of the drills, an unhealthy if not dangerous thing for the workmen. In some instances of this kind the men have been overcome with carbonic acid gas. This is known as the 'inflaming' of compressors.

Temperature, since the time of Galileo, has been measured by the expansion of mercury in a glass tube. The unequal expansion is divided into degrees and values are based upon the position of two fiducial points. Galileo had a scale of 360 degrees, the lowest point based upon some freezing mixture and the highest representing the warmest day of summer. Fahrenheit had several scales. In the one finally adopted the zero is based on the temperature of the coldest day of the year 1709 in northern Europe. Réaumur used melting ice and boiling water, dividing the distance into eighty degrees. Celsius, using the same points, divided the distance into one hundred degrees, with the zero at the boiling point. This scale is often referred to as identical with the Centigrade, but this is a mistake. Linnaeus modified Celsius' scale, making the zero indicate the temperature of melting ice and one hundred degrees that of boiling water. This is the widely used Centigrade scale. Concerning the Fahrenheit scale, it may be noted that it has practically lost place in scientific usage today. Furthermore, in all our thermometric scales the so-called fixed points are not truly fixed.

Special Correspondence

BULAWAYO, SOUTH AFRICA

Gold Output of Southern Rhodesia. — Important Flotations. — High-Grade Ore in Matabeleland.

The value of the mineral output of Southern Rhodesia for August was £216,562, as compared with £214,075 for July. The gold was valued at £191,423, or £3810 less than for the preceding month. To those unfamiliar with the present situation in Southern Rhodesia it may seem contradictory that although there has been far more activity the past few months than at any other time in the history of Rhodesia, and that while Rhodesian mining properties are in greater demand than ever, the gold output has declined steadily since last March, when the value of the gold production was £288,385. The April return was £288,213; for May, £224,888; for June £214,709; for July, £195,233; and for August, £191,423. The continued decline is largely due to the fact that the number of gold producers has fallen off greatly during the last seven months, as many properties then in the hands of small syndicates and regular producers, have lately been taken over by wealthy companies. These large companies have suspended work at the small plants and have adopted a policy of vigorous development to open the claims acquired and to prepare them for larger crushing equipment. Another factor which has greatly affected the output for the past two months has been the closing down of the mill of the Globe & Phoenix company, which was the largest producer in the country. This was necessary owing to the condition of the main shaft. Repairs have been completed and the property will continue to contribute largely to the gold output of Matabeleland. The results of recent development at the 16th and 17th levels point to the persistence of the orebody to great depth, and thus far the gold content of the vein is higher at depth than nearer the outcrop. Before the hanging up of the 40 stamps of this company the average monthly return from January to June was about £30,000, whereas in August the company's output was less than £2000, derived from the re-treatment of sand. Apart from gold, the following mineral output is reported by the Rhodesia Chamber of Mines for August: silver, 19,312 oz., £1985; lead, 63.7 tons, £701; copper, 4.37 tons, £218; chromic iron, 6248 tons, £13,875; asbestos, 30 tons, £300; coal, 16,794 tons, £8060.

Since the beginning of 1910 fully 40 new Rhodesian limited liability companies have been registered in London, Salisbury, and Pretoria, and new flotations are still being announced. Never in its history has Rhodesia attracted so many prospectors and speculators, and so much capital as at present. All over Matabeleland and Mashonaland, agents of Johannesburg, Bulawayo, Salisbury, and London firms are to be found, and blocks of claims have changed hands at extraordinary figures. Many fortunes have been made and men who two or three years ago were struggling to make both ends meet with a 2 or 3-stamp mill, are now wealthy and have left for Europe with large checks signed by well known South African magnates. Among the most important deals concluded of late were the sale of the Lonely mine owned by Paica and Aserman to the Rhodesia Gold Mining & Investment Co. for £125,000 cash and 75,000 shares; the Csardas mine to Abe Bailey for £50,000; and of the Colossus mine to Mr. Arnold, of Salisbury, for about £30,000. Other important transfers are reported in connection with the Cam and Motor mines, the Masterpiece, the Planet, the Bell, and properties in Enterprise district. Nearly all these ventures have been floated as limited liability companies, and in consequence two or three millions sterling in working capital has been raised in South Africa and London for Rhodesian mines. Among the best known South African magnates who have recently invested largely in Rhodesian mining is R. H. Hollins of London and Johannesburg, who has acquired, among other properties, the Bush Tick, a big low-grade property near Essexville, in Matabeleland, which is to be equipped with one of the largest slime plants in the world, and the Shankuru, Planet, and Dawn mines in Mashonaland. These three latter and certain other claims purchased by Mr. Hollins are being floated. A new company has been registered in Salisbury with a capital of £350,000 and a working fund of £150,000 to take over and work these mines which, although they do not promise to develop into large properties, are promising ventures. The Bush Tick, however, may reasonably be expected to prove to be one of the biggest mines in Matabeleland and will no doubt be the subject of important flotation at an early date. The development of the Lonely Reef mine in the Babi district of Matabeleland continues to be most encouraging. During August a 10-stamp battery crushed 1220 tons; the yield from the plates was 631 oz. and from sand 319 oz. The equipment is being largely increased and among the features of the new plant will be Pachuca tanks—the first, I believe, to be installed in Southern Rhodesia. The capacity of the new equipment will be 4000 tons per month, and it is anticipated the new plant will commence work in January. The consulting engineer, C. B. Kingston, reports that at the end of June the ore reserves were 36,898 tons of an average assay value of 20.9 dwt. over a stoping width of 36 in. He calculates that by the end of the current year the ore blocked out will have been increased to 70,000 tons. H. B. Maufe, the recently appointed Chief of the Geological Survey of Southern Rhodesia, is at Salisbury conferring with Sir William Milton, the administrator, on the question of whether the survey shall be commenced in the Matabeleland or the Mashonaland province. Mr. Maufe has already made a preliminary investigation of the geological conditions around Bulawayo and Gwelo, but the systematic geological mapping of the country has not yet been commenced. The British South Africa Company's directors are, in addition to the Geological Survey, employing prospectors to exploit various portions of the company's territory, and it is anticipated that much valuable geological data and not a few important discoveries will result from these expeditions of research.

DAWSON, YUKON TERRITORY

Good Season Closed.— North Fork Power Co. — Methods of Excavation.—Boyle Concession.—Largest Dredge in the World.

The past season has been one of the most active that this district has witnessed, and at its close all work contemplated for this season was finished. This is rather unusual, since construction work nearly always extends over a longer period than planned. This is especially true in this northern country. A particularly notable undertaking is that of the North Fork Power Co. controlled by A. N. C. Treadgold, of London. The plant of this company will be supplied with water through a ditch six miles long tapping the North Fork of Klondike river at a point thirty miles from Dawson. The ditch when completed will deliver 20,000 inches of water under a head of 235 ft. and approximately 10,000 hp. will be developed. The plant will be of the latest design throughout and capable of supplying sufficient power for this district for all mining purposes. Construction is under the immediate charge of H. G. Boardman, who for the past four year was chief electrician for the Yukon Gold company. The ditch was excavated by means of two Thew steam-shovels in charge of David Eliott, a man of resource and long experience. Many difficulties were overcome, chief among which was that of disposition of the spoil, the ditch being large, 25 ft. wide on the bottom, 5 ft. deep, and with a slope of 1½ to 1. The country through which the ditch passes is almost flat. A second and almost as serious difficulty was the presence of frozen ground at points throughout the length of the ditch. The former difficulty was overcome by raising the shovel arm to its full height directly opposite the piled-up material on the lower bank, and then extending the arm horizontally to its full length, the top dirt, being thus pushed outward by the bucket, made room for a new load. This operation was repeated as often as possible. This involved delay for the shovel, but in most instances proved satisfactory. Where this method would not suffice, a steam scraper of one-half

cubic yard capacity was brought into play, but owing to the immobility of the device this method was not as satisfactory as the first where the latter would work. The frozen ground was overcome by the use of powder and by thawing. Where the latter was done steam was injected through pipes of ¾ in. diam. These 'points,' as they are called, are made of hydraulic steel pipe and have solid heads 6 to 8 in. long welded on the upper end. Immediately below this head and at right angles to the pipe a nipple of smaller diameter 3 to 4 in. long is inserted. The other end of the point is sharpened by drawing the pipe together until only a small opening remains through which the steam may pass. To the nipple is connected a steam hose of suitable length which is attached to the supply pipe. These points are made in lengths suitable to the depth of ground to be thawed. They are placed in a vertical position and the steam finds its way through the point to the frozen material, which it quickly thaws. The point is then driven down by tapping with a hammer on the solid head until the desired depth is reached. It is then allowed to 'sweat,' as it is termed, for several hours, according to the character of the deposit, after which it is drawn up and the operation repeated elsewhere. As many points as desired may be used. They are placed 8 ft. apart and are supplied with steam by a systematic distribution of parallel lead pipes. Approximately one horse-power boiler capacity is required per point. The elevation at the intake of the North Fork ditch is not more than 500 ft. above the general mining field, and as a result the plant will run during the entire open season, the freeze-up at plant and mining field occurring simultaneously. Where the elevation of the intake is considerably greater than the point where the electricity is employed, the open season is necessarily shorter, and power is cut off a week or two before mining would otherwise have to stop. In the spring power may be delayed an equal length of time. The Yukon district is fortunate in its power possibilities, as the tributaries of Klondike river are capable of supplying more power than is likely to be required for a long time.

Another interesting feature of this year's work was the installation of a 15-ft. dredge, built by the Marion Steam Shovel Co. on the Boyle Concession. This dredge is the largest boat yet constructed, and will dig approximately 10,000 cu. yd. per day. The work of assembling this dredge is in the hands of Howard Brenner, who came from the Marion works for this purpose. He chose his workmen and mechanics from the men living in this country and was able to find skilled men for every class of work connected with the building of the boat. The transportation of machinery from Dawson to the point of construction on the Boyle Concession, a distance of seven miles, was no easy matter even over the excellent roads of the Klondike. Some idea of the magnitude of this dredge may be gained from the following weights: two spuds, each 27 tons; points of spuds, each 5 tons (a total spud weight of 32 tons) ; lower section of the bucket ladder, 17 tons; buckets (between 70 and 80 in number), each 4100 lb. The total weight of the loaded ladder will be 275 tons; the weight of tumblers, lower 5 tons, upper 7 tons, the latter carrying a 25-in. shaft; total weight of dredge, approximately 900 tons. This is the second dredge on the Boyle Concession. The first, a 7-ft. Marion boat, has been successfully at work for five years, and is still fit for long service. Both boats are electrically driven, and will have a combined capacity of 14,000 cu. yd. per day for the entire season, which on this property is at least six months in the year, on account of unfrozen condition of the deposit. There are other things under way for the future, but at present little authentic is known of them. The great opportunities of the Klondike and Alaska are gradually becoming known, and it is to be hoped that they will be carefully exploited before investment. Thorough prospecting and preliminary work are most essential, and these investigations should be intrusted to competent men familiar with the unusual conditions. Much money will be saved and disappointment avoided if prospective investors will carefully investigate conditions before plunging into a region little understood by outsiders.

TORONTO, CANADA

Cobalt Discoveries.—Porcupine Mines.—Discoveries at Hoban.—Moose Mountain.—Nova Scotia Iron.

Recent favorable news from the La Rose mine brought the stock up to par again last week in a generally dull market. The reports have been fully confirmed as to the finding of a rich vein at the 170-ft. level, paralleling the main vein. It has been cut at eight points on the 157-ft. level and also at the 62-ft. level, and opened for several hundred feet in length. The average width is 4 to 5 in., and the ore assays nearly 4000 oz. in silver. Rich ore has also been struck at the 188-ft. level of the Lawson property. The latter discovery is regarded as of importance to the Hargrave mine adjoining, as Hargrave's No. 11 vein runs west toward the Lawson line. It is a strong vein, but has not been opened, operations being principally confined to No. 1, 2, and 3 veins, which have lately been yielding well. The mine is taking a good place among the active shippers. At the Beaver the main shaft and the winze are both down 300 ft. A cross-cut was recently driven on the 200-ft. level to open a vein cropping at the surface, which showed rich ore at a distance of 110 ft., and a good vein, 6 in. wide, of high-grade ore has also been found by cross-cutting on the 250-ft. level near the Temiskaming line. Seven drills are working double shift with a force of 80 men. A contract to sink to 400 ft. has been let. Foundations are being laid for an addition of 20 stamps to the Northern Customs concentrator which will increase its capacity to 200 tons of ore per day. The Townsite has made a contract with the company to treat 50 tons of ore per day. The bullion shipments from Cobalt are steadily increasing. The Provincial has found good ore at 175 ft., an adit at this depth being driven between two veins, each 2 or 3 in. wide and about 4 ft. apart. These veins have merged and show increased silver content. The Wettlaufer in the South Lorain area has a pay-shoot 126 ft. long at the 220-ft. level, yielding 4000-oz. ore.——Among recent visitors to Porcupine was William Frecheville, who after a brief inspection of the camp stated that he was satisfied that there were at least two coming dividend-payers among the properties undergoing development, and a number of highly promising prospects. Interests identified with the Dome mines have taken an option on the six Shillington-McIntyre claims in the Pearl Lake area. The purchase price is given as $400,000. The Davidson properties adjoining the Crown Chartered have been bought by an English syndicate.——Rich gold discoveries are reported in the neighborhood of Hoban, a point on the main line of the Canadian Pacific railway, 120 miles north of Sault Ste. Marie. William Norquist was the discoverer and located five claims before the news got out. There has since been a rush and many prospectors from Haileybury and Sudbury have gone into the country.—— There is increased activity in the iron and steel industry. Numerous mergers and expansions of manufacturing enterprises have stimulated iron mining. The Moose Mountain Mining Co., which is working large iron-ore deposits at Sellwood, to the north of Sudbury, has decided to supplement the process of magnetic separation, now used in refining the ore, by the Gröndal process of wet separation. When the new plant is installed it is expected that their output of refined ore will be increased to about 1000 tons per day. The Atikokan Iron Co., of Port Arthur, will operate its furnaces all winter, instead of closing for the season as has hitherto been done. Railway communication will enable the company to obtain a steady supply of ore from the Atikokan mine. Sydney Davies, an expert from Newcastle-on-Tyne, England, is in Canada looking into the possibilities of securing a supply of Canadian steel for British manufacturers and shipbuilders. He has been examining the iron ore deposits of the Gatineau in the Ottawa district. Boring operations on the submarine iron ore areas of the Nova Scotia Steel & Coal Co., Wabana, have shown that the lower bed is 20 ft. thick and carries 3 to 4% more metallic iron than the other workings. This lower seam has been proved to extend about 3000 ft. into the company's area.

LONDON

Rio Tinto's Curtailment.— The Cobar Mines. — New Tin Promotions.

The directors of the Rio Tinto company, owning the premier copper mine of Spain, have issued the usual autumn report. They announce an interim dividend of 25% on the ordinary shares. A year ago the interim dividend was at the rate of 30% and the total dividend for 1909 was 60%. The information relating to the intended restriction of the output of metallic copper is of particular interest. It appears that the demand for sulphur ore is greatly increasing, so, in view of the low price of copper, ore of lower copper content is now being mined. Thus less copper will be marketed, the decrease for 1909 being estimated at 4,480,000 lb. The directors note that this action on their part has had some influence on the American producers and they are able to forecast a general diminution in the production. As regards the profits of the company, the directors indicate that they will be much less for 1910 than for 1909. The report also mentions that the work of removing the overburden is being hastened, and it is recorded that the recently increased reservoir capacity has enabled the mine and smelter to get through an unusually dry summer without any shortage of water.——The Great Cobar copper mine is one of the most important mining propositions in Australia. It yielded handsome profits for many years to local owners, and most of the London promoters cast longing eyes on it. The owners, however, wanted a high price, and wanted it in cash, so that it was beyond the reach of most of the proposers. Eventually a group of financiers consummated the deal, and an English company was formed in 1906 to acquire the property. The purchase price was £800,000 in cash and £206,000 in shares and debentures. J. D. Kendall, C. M. Rolker, and W. J. Barnett reported on the property, and the first named became consulting engineer. The Lithgow refining works and the Chesney copper mine were also purchased. The company proceeded to erect modern blast-furnaces, and large sums were spent for the purpose. Unfortunately, the design was not adapted to requirements, and in a great number of ways the working of the plant broke down. G. H. Blakemore, the manager, resigned, and subsequently J. D. Kendall followed suit. H. C. Bellinger of Montana was appointed manager at the beginning of 1909, and, being a skilled copper metallurgist, he has been able gradually to rectify the faulty construction. The report of the company for 1909 has just been issued, its appearance having been delayed by the disarrangement of operations caused by the Australian coal strike, which stopped all work at the beginning of November of last year. The directors, however, issued concurrently an interim report, bringing information up to date, and at the meeting of shareholders held on October 12, the present position was still further elucidated. The mistakes in the design of the plant, together with the coal strike, have cost the company large sums of money, which have been provided out of revenue. Owing, however, to the imminence of the time when £100,000 a year has to be provided for the redemption of debentures, the directors have considered it advisable to recommend the creation of 30,000 new shares of £5 each and to hold them in reserve in case it might be desirable to issue some of them in exchange for debentures. It should be recorded here also that, four months ago, the property of the Cobar Gold Mines was absorbed. This was an important move, for it gives the company a liberal supply of siliceous flux containing 10 dwt. gold per ton in place of the barren flux which has hitherto been purchased and hauled from a considerable distance. During the ten active months of 1909, 163,449 tons of Cobar ore and 40,928 tons of Chesney ore, together with 42,718 tons of 'returns' were smelted, and the amount of metal shipped was 5072 tons copper, 14,452 oz. gold, and 83,207 oz. silver. The most recent news is that the smelter and mine are now in a position to produce and treat 40,000 tons of ore per month and produce 850 to 1000 tons of copper. The ore reserve on August 31 of this year was 2,877,000 tons in the Cobar and Chesney mines averaging rather under 3% copper (figures showing a large increase over those of December 31 last) as well as 250,000 tons of gold ore in the Cobar Gold mine. The main shaft at the Cobar is 1170 ft. deep, and a level is being opened at 1150 ft. where the ore is as good as anything above. It is intended to sink farther and start levels at 1300 ft. and 1450 ft. Diamond-drilling shows that the lode in several of the levels can be worked profitably to a greater width than was at first supposed. The accounts at December 31 showed a profit of £53,938, out of which £41,640 went as debenture interest, and £11,700 was devoted to filling some of the stopes with waste.——Attention has been attracted once more to the Briseis Tin company, which was floated in 1899 by the Venture Corporation for the purpose of acquiring tin gravel deposits in the northeast of Tasmania. The price paid by English shareholders was about ten times as much as the Australian intermediary vendor paid for the property, and the results have never come up to expectations. The company operates the adjacent gravels belonging to the New Brothers Home No. 1 Co., and receives 58% of the proceeds. In 1909, as the tin-bearing gravel was approaching exhaustion, the scope of operations was broadened and the words 'General Mining' were added to the name, at the same time options on gold-gravel properties in Victoria being obtained. The capital of the company is £600,000, and the total dividends to date amount to 46¼%. The report now issued covers the year 1909. It includes reports by the consulting engineers Lake & Currie, and by Lindesay C. Clark, the general manager. Concurrently an additional report by David Currie is issued giving the results of his investigation made two months ago. The report for 1909 shows that during the year 888,050 cu. yd. of tin-gravel and overburden in about equal quantities were removed, as compared with 1,115,300 cu. yd. in 1908, the decrease being due to the cemented nature of the gravel and the increased hardness of the basalt overburden. The south section at Briseis is practically exhausted and the No. 1 will follow suit shortly. The output of black tin was 1102 tons as compared with 1395 tons, the metallic contents of which were 808 tons and 1020 tons, respectively. Of the metallic tin, 767 tons came from the Briseis property in 1909 and 914 tons in 1908, the remainder coming from the No. 1. The Briseis company takes 58% of the produce of the No. 1 and pays 42% to the owners. The total income of the Briseis company for 1909 for the tin property was £105,953, and the expenditure at the mine £37,668. The directors report that the Wallace gold-gravel properties in Victoria were acquired during the year and that a third dredge has been built. Much preliminary work is being done and £22,409 has been spent on capital account against a recovery of £4437 in gold. After payment of London office expenses, taxes, etc., and allowing for depreciation, the balance of profit is £33,852, of which £20,000 has been carried to reserve and £15,000 distributed as dividends, being at the rate of 2½%. Since the end of the year the output of tin concentrate has been maintained at practically the same rate, and at the Wallace mine 252,890 cu. yd. yielded gold £3935. Mr. Currie's report states that the southern section of Briseis was exhausted in June of this year and that in the northern section, which as mentioned above consists of cemented gravel, there was in September a reserve estimated to contain at least 500 tons of black tin. No. 1 property was worked out in June. With regard to other resources, the borings at Krushka's Flat indicate the presence of over a million cubic yards of ground, some of which is old tailing, averaging 2½ lb. of black tin per cubic yard. The Ringarooma property presents many difficulties and work has not advanced far. It is proposed to strip one face so as to ascertain the general nature of the deposit, and its ultimate exploitation will have to be further considered. Mr. Currie estimates that during the next three years an output of 45 to 50 tons of black tin can be maintained from the northern Briseis and Krushka's Flat. Much interest now centres in the development of tin-bearing gravel mines in Nigeria, Africa, where a large tonnage of payable ground is said to be available.

MEXICO

Interesting Statistics.—Extensive Operations in Altar Placers. — New Oil Development.

A recently issued statement, covering in detail the foreign commerce of Mexico in the fiscal year 1909-10, shows that the exports of mineral products amounted to ₱156,520,917.84, or over 60% of the total. The year's exports had a total value of ₱260,056,228. The mineral exports of the last fiscal year represented a substantial increase over those of the preceding fiscal year, 1908-09, and a slight decrease compared with those of 1907-08. The totals for the two years were, respectively, ₱144,272,825.52 and ₱158,409,327.07. The statement also shows that the balance of trade between Mexico and the United States during the fiscal year was considerably in favor of this republic. While Mexico's exports to the United States amounted to $196,978,639.52, or 75.74% of the total exports, the imports from the United States had a value of only ₱112,878,362.06, or 57.93% of the total imports. In this connection it is interesting to note that while Germany sold Mexico products representing 10.35% of the total imports, Germany's purchases from Mexico equalled only 3.25% of the total exports. The corresponding percentages for France were 8.98 and 4.72, and for Great Britain 11.42 and 10.97. The lack of metal manufacturing in Mexico, notwithstanding the country's great mineral production, is brought prominently to public attention by figures showing imports of manufactured articles of gold, silver, and platinum to the value of ₱3,235,723.32, of copper to the value of ₱3,015,454.57, and of tin, lead, and zinc to the value of ₱706,797.15, a total of ₱6,957,975.04.——Equipment capable of handling, according to estimates, up to 5000 tons of dry-placer material in 24 hours will be installed by the Neill Development Co. of Spokane, Wash., at the Palomas placers in the Altar district of Sonora. The company was formed early this year. The equipment will include 8 Quinner pulverizing machines, tables for dry concentration, and a complete system of belt conveyors for handling the cemented gravel and tailing. The plans, which have been prepared by Los Angeles engineers, call for the erection of an electric-power plant at the coast and the transmission of current 27 miles. The conglomerate will be carried to five Quinner machines for disintegration, the product passing to dry concentrators, and later the tailing will be reground in three Quinners and reconcentrated. Several areas of cemented gravel are included in the company's holdings. The one to be worked first has an area of 3,000,000 sq. ft. and an average depth of 50 ft. Within the last 60 days titles to a number of important placer denouncements in the Altar district have been issued, and plans are in progress for the equipment of some of the properties with pulverizing and dry concentrating plants. The denouncements were made early in the year.——Mine water is to be utilized by the Tajo Mining Co., of New York, operating in the San Sebastian district of Jalisco, in the generation of electric power for mining and milling. The company is driving a long adit to cut the old Tajo vein at depth, and is now in 2200 ft., and through this adit much water is flowing. It is to be carried in iron pipes of 10, 11, and 12 in. diam. for a distance of 3000 ft., and will operate Pelton wheels under 600-ft. head. It is estimated that the volume is sufficient to generate 250 hp., enough for the company's mining and milling requirements. The pipe and power equipment are on the way to the mines, 100 miles distant from the railroad at San Marcos. The company is increasing the capacity of its concentrating and cyaniding plant to 120 tons daily.——The transmission of power to the Etzatlan and Hostotipaquillo districts of Jalisco will be commenced shortly before the opening of the new year, according to the latest estimate of the Chapala Hydro-Electric & Irrigation Co., of Guadalajara. Pending the completion of its new plant, power will be supplied from an old plant at the Juanacatlan falls of the Santiago river, and the transmission will be at 30,000 volts. At this voltage the loss is expected to reach nearly one-third, but the company is willing to stand it, particularly as penalties to mining companies for failing to deliver power more than a year ago will be stopped. With the completion of the new power plant the transmission will be at 70,000 volts. In connection with the important Mines Company of America-Dolores-El Rayo merger, it is now explained that the properties of the La Dura Mining & Milling Co. in Sonora, taken over some months ago by the Mines Company, will be held equally by the three merger concerns. Payments of $400,000 have been made on the La Dura properties out of the earnings of the three companies. The reduction plant of the La Dura is being overhauled, and new equipment will be installed. Telephone lines connecting the plant with the Gloria and Prieta mines are being built. It is stated that the Mines Company of America is planning to increase its milling capacity from 9000 to 16,000 tons per month. A report of the Dos Estrellas Mining Co. for the five weeks ended October 1 shows a production of ₱1,189,908.54. The expenses for the period were ₱390,220.24, leaving a profit of ₱799,688.30. The ore milled totaled 43,545 tons, and shipments of 73 tons of rich ore were made to the smelter. In October the Dos Estrellas paid dividends of ₱4.50 per share, a total of ₱1,350,000.

Mexico.

SALT LAKE, UTAH

Utah Copper Co. Curtailing. — Daly West's Quarterly Report. — Litigation Compromised.

The quarterly report of the Utah Copper Co. shows a production of 23,194,921 lb., a monthly average of 7,731,640 lb., which is about 2,000,000 lb. less than the preceding quarter, due to the curtailment of production inaugurated August 1. The average copper content of the ore during the quarter was only 1.5%, and for September 1.4%. The cost of production was 8.23c. per pound against 7.53c. for the preceding quarter. This increase in cost was due to the smaller production and the lower grade of ore treated. The total net profit for the quarter was $1,329,966.88 and the dividends paid $1,168,882.50. About 83% of the ore was mined by steam-shovels and the remainder by underground methods. Four shovels are stripping the ground acquired from the Boston Con., but it will be some time before this portion of the property will be ready for steam-shovel mining. The alterations in the Magna plant have been completed and it now has a normal capacity of more than 10,000 tons per day. Alterations have been commenced at the Arthur plant, which is, in consequence, operating at only part capacity. It will be about the first of the year before any of the remodeled part of this plant will be in operation. Grading on the open work of the Bing-

ham & Garfield railroad is nearly completed, and connection between the Magna plant and the San Pedro railroad will be finished by the end of the year. The tunnels at the Bingham end of the line will be driven during the winter and should be completed by April, so that the company will be shipping over its own line some time during the second quarter of 1911. The report of the Daly West for the third quarter shows a net profit of $34,734.17, against which is dividend No. 52 of $54,000, so that there is a debit of $19,265.83 in the cash balance for the quarter. During September the mill was closed down except for one shift, causing material falling off in receipts. It will be operated on this schedule indefinitely, and the report states that, owing to the large amount of development being done, actual operating expenses will not be met under these conditions. The ore opened up on the 1900-ft. level proved to be richer than that on the 1700 and 1800-ft. levels, but was not found in the quantity expected. Unless something unforeseen occurs, it is reasonable to suppose that Daly West has paid its last dividend for some time to come. In the suit of the Uintah Treasure Hill against the Silver King Coalition, a stipulation has been filed which provides for the sale of the twelve claims in dispute. The claims will be sold individually at public auction and the proceeds will be apportioned by the court when the suit is decided. The Uintah Treasure Hill claims an undivided two-thirds interest in the property and asks that it be reimbursed for $28,700 spent in developing it. This company has levied an assessment of one cent per share. Colorado has made a find in almost unexplored ground. A drift sent out on the 300-ft. level cut ore near the Sioux Con. end-line. While the discovery was made near the boundary line, the supposition is that the vein is overhead and that the ore will make back along the drift. The Sioux has worked out its portion of the vein at this place, so that this development will not affect the latter company. Beck Tunnel has levied an assessment of one cent per share. The Rainbow mine, in Mormon Basin, Idaho, owned by the Commercial Mining Co has been bonded to the United States Smelting, Refining & Mining Co. for $1,050,000. By the terms of the agreement the United States company has four months in which to make an examination, and if it then decides to take over the property, will make a cash payment of $250,000. At the annual meeting of the South Utah, F. A. Schirmer was succeeded on the directorate by Hugo Hoffsteadter, and L. A. Kramer by Samuel Newhouse. No report was issued, as the first unit of the remodeled mill only went into operation September 1, and the second unit September 16. Up to October 21, 730 tons of concentrate was shipped to the International smelter at Tooele, but the management is expecting to produce 1000 tons per month. Since the reorganization the mill has been remodeled and the company has $200,000 working capital in the treasury. An attempt is being made by Salt Lake and Los Angeles capitalists to organize an independent smelting company.

NEW YORK

Politics and the Market.—Copper Production.—New Mill for Alaska.—Cerro de Pasco.

Political possibilities were potent market factors before the recent election. Wall Street's desire to repudiate Mr. Roosevelt has been so fully gratified as evidently to somewhat overawe the very interests who were loudest in demanding his defeat. It is as yet too early to estimate the market effect of the political landslide, though it is apparent that there is no pent-up 'bull' enthusiasm to be liberated.

In the mining market there is much to overcome. Mining-share operations have left a multitude disappointed, angry, and bewildered. There have been too many campaigns carried on with consummate skill, ending in approximately total losses; too many of the type of Ely Central, Cobalt Central, Nevada-Utah, Trinity Copper, and a host of other specific instances, to say nothing of the great public, which got into the cheaper Goldfield issues, and who, for the most part, is yet owner of stock certificates purchased at bottom prices. If out of all the spectacular advertising campaigns there comes some education of the public, some idea of the value of the right kind of publicity, some idea of mine valuation, financial requirements, and management, rather than an angry sense of loss and a complete refusal to regard the mining industry in its true light, then, perhaps, the losses suffered will be cheap experience in the end.——The Copper Producers Association's figures covering the month of October were satisfactory, though the result was attained in rather unexpected fashion. Following a decrease in foreign accumulated stocks during October of 12,407,360 lb., the decrease in surplus in this country was 9,531,800 lb., cutting down the world's supply by 21,939,160 lb. to 337,327,194 lb. The unexpected element was the increase in production, which for the month totaled 126,469,284 lb., a figure exceeded but twice during the current year. The situation was saved by the consumers, who took 136,001,084 lb.—67,814,172 lb. for domestic use, 68,186,912 lb. for export. The figures are rather disconcerting for those who have been crediting the betterment in copper to an understanding among the large producers. In October and November it was expected that the refinery output would begin to show the effect of restriction. November figures will, therefore, in view of last month's output, be looked for with some anxiety.——Utah Copper costs continue to exceed those of Nevada Consolidated materially. The report for the quarter ended September 30, shows an average cost of 8.25c. per lb. against a cost of 7.05c. for Nevada. The average monthly production was 7,731,640 lb. of copper. Net profits for the quarter were $946,026, in addition dividends received from the Nevada Consolidated were $371,730, making a total net profit of $1,329,967. Four steam-shovels are stripping on the Boston Consolidated ground and three more are to be started as soon as possible.——The Tennessee Copper Co. is contemplating making a refunding bond issue. There are now outstanding first-mortgage bonds to the amount of $350,000, and $600,000 in short-term notes. A special meeting has been called to provide for the issuance of $1,500,000 first-mortgage bonds to retire all of the outstanding obligations, the balance of the proceeds to go into the treasury. Tennessee Copper represents a total investment of nearly $12,000,000, of which about one-fourth has been expended on the acid plant.——Ray Central is still in the market with its $2,000,000 bond issue. Underwriters are asked to take over the management of the property. During the time that Ray Central was under option to the General Development Co. the issue had a large active following. In the present situation, therefore, there have been a number of irresponsible market sharpshooters endeavoring to secure an underwriting of Ray Central, with the hope of scalping trading profits in a manipulated market.——Ely Central, selling but a short time ago at $4 per share, is in the throes of reorganization. It is proposed to shareholders to form a new company, of which one share of stock is to be exchanged for one share of Ely Central and 25 cents. This assessment is considerably more than the present price of the stock. The house of Scheftels & Co., recently raided by Federal authorities, is said to have heavily oversold Ely Central and to have been short a large amount of stock at the time the authorities descended upon them. It is believed the same interests, in the hope of defeating prosecution, are now engineering the present move in the hope of eventually doing something with the stock in case they can get on their feet again.——The California Nevada Copper Co., which is erecting the big mill on the Ebner gold mining property, near Juneau, Alaska, has purchased the entire capital stock of the Humboldt Gold Mining Co. The property consists of 32 acres of ground on both sides of Gold creek, on which some development has been done, and a 5-stamp mill built. The ground was particularly desired by the California Nevada, as, by the purchase, the latter acquired complete control of the water-power on Gold creek, where 3000 hp. can be developed.

COLORADO SPRINGS, COLORADO

Taxation.—Coal Mine Disasters.—Clear Creek Mines. — Drainage at Cripple Creek.—Treatment Rates.—An Important New Coal Company.

Political issues have so occupied the public mind and press that the industries of the State have remained almost unnoticed. The Colorado branch of the American Mining Congress took occasion recently to express its dissatisfaction with the present system of taxing mining property. It was an opportune time to bring forth such a discussion, as legislators seem more attentive to the wants of their constituents before than after election. It is a fact that some properties that are struggling along, barely on a paying basis, are burdened by a tax levy on gross production instead of net income.——Two serious coal-mine explosions have occurred during the past month in the Trinidad field. The first, on October 9, was at the old Starkville mine, five miles southwest of Trinidad. This property is one of the oldest and most extensive in the district. It is operated by the Colorado Fuel & Iron Co. The mine was badly damaged by the explosion and 56 men were killed. The State Mine Inspector has reported poor ventilation and an accumulation of unsprinkled dust in the main haulage-ways. Exactly a month later the No. 3 mine of the Victor-American Fuel Co. at Delagua was wrecked by a terrific explosion which caved the main slope for several hundred feet. This explosion is believed to have been caused by a fire which broke out in the old workings. At last reports 81 men were believed to have perished in this disaster. Heroic work on the part of the crews of the C. F. & I. rescue car and of the Bureau of Mines car, which had arrived in Denver less than a week before, was responsible for saving several of the entombed miners. As one observes the elaborate precautions taken to rescue men after an explosion, he wonders if equal precautions are being exercised to prevent such accidents.——Rich finds and heavy shipments are reported from all the metal-mining camps of the State. Leadville has largely increased its tonnage by shipping the zinc ores recently discovered in many of its old mines. The new camp of Beshears, near Georgetown, claims a mine in the Esconado which has shipped a ton of $82 ore to the sampler at Georgetown. A few of the companies are laying in supplies for winter development. The Malm dry-chlorination plant is still incomplete and many are becoming impatient at the repeated delays. With this plant not yet ready for business and the Modern smelter at Utah Junction sold under foreclosure, the producers in the upper Clear Creek district are left with only the Golden and Denver plants to choose between.——The Cripple Creek deep drainage adit has begun to benefit the camp. The drill-hole from the bottom of the El Paso shaft to the lateral from the tunnel was finished on November 5. The lower workings of the mine have since been slowly draining. The breast of the adit is now very wet, and the main watercourse may be broken into at any round of holes. In the latter part of September the U. S. R. & R. company announced a cut in treatment rates on low-grade ores at the Colorado City plant. The Portland company immediately met the rate. The Golden Cycle plant did not attempt to meet the rate and has lost some low-grade ore as a result. Now the Portland management announces that its old rate will henceforth be in effect, as there is no profit in treating the ore at the lower figure. The production from the district for October was 68,775 tons having a gross bullion value of $1,427,275. The proposed aerial tram from the Golden Cycle mine to its mill in Colorado City is still under discussion.——A new company which rivals the C. F. & I. in the scope of its proposed operations has been incorporated by J. D. Milliken and associates. It is known as the Colorado & Wyoming Coal Co., and is capitalized at $6,000,000. The company will operate in Adams, Weld, Larimer, Huerfano, Fremont, Las Animas, and Routt counties in Colorado, and in Albany, Carbon, Natrona, Converse, Big Horn, and Uinta counties in Wyoming. Its incorporation papers permit it to engage in mining and the sale of coal, the manufacture of coke, and the building of smelters.

BUTTE, MONTANA

Anaconda Buying New Property.— Extensive Improvements Unper Way.—Copper Output for October.

The Anaconda Copper Mining Co., within the past few days, secured several properties by purchase which includes the Old Glory, a developed mine in Centerville district, through the purchase of a seven-twelfths interest, the company having secured five-twelfths when the Trenton and Red Metals companies were purchased. The Old Glory lies between the Snoozer and Raven mines, having been located on a northwest and southeast discovery vein, while the Snoozer and Raven are east-west locations. The Old Glory has produced some ore. The Anaconda company has also purchased the Emily and Millview lode claims lying just north of and adjoining the Badger State and Auraria claims of the Anaconda company. The Anaconda company is also developing the Badger State mine, formerly one of the Boston & Montana properties, and reports are that an important copper vein is being opened on several levels down to a depth of 1800 ft. In addition to the Emily and Millview, the Anaconda company has bought from the Largey estate the Polly lode claim, a half interest in the Torrid, one-half interest in the Tropic, five-twelfths in the Maud & May, and one-eighth in the Sioux Chief, all fractional claims lying within groups of the Anaconda company properties. The Sioux Chief lies just south of and adjoins the Tuolumne.——The Heinze Basin Reduction Works is having some trouble as a result of the $145,000 claimed by the State Savings Bank as long overdue on a note. The Sheriff of Jefferson county, in which the property is situated, has attached the millsite of the company, water rights, and improvements, and the Katie, Kissing-Bug, Canyon placer, and Klondyke placer claims. The note was signed by the president and treasurer of the Basin company.——The Butte Central Copper Co. has commenced sinking the shaft 500 ft. The property consists of the Ophir mine which is now down 500 ft. Men are at work on the several levels between the surface and the 500-ft. level. ——Expensive improvements are being made by the Anaconda Copper Mining Co. It will cost over $1,000,000 to install the electric system and the air system to operate the hoisting engines. Compressed air will be used in the engines instead of steam. Twenty-five air receivers, each 30 ft. long by 10 ft. diam., have been installed with a dozen huge compressors, in a building more than 300 ft. long, sufficient air storage to hoist every man in the Anaconda mines in the event of accident to compressors or suspension of the electric current. In conjunction with the air-compressor plant a water tank has been erected which is 100 ft. diam. and is built entirely of steel.——According to advices from Wallace, Idaho, Heinze's Stewart mine has augmented its output and the force has been increased to 125 men. According to report, 1000 tons of concentrate has been turned out monthly by the Wallace mill, at a net profit of $15,000. This was accomplished working one shift. A second shift has been added and the daily output of ore increased to 280 tons and the monthly output to 1200 tons of concentrate.——Butte & Superior stock is still almost stationary. The mine is shipping ore daily to the Basin concentrator, with good results, and it is understood that the company is more than making all operating expenses. The Butte & London Mining Co.'s special meeting, held to consider the raising of money to meet an indebtedness by mortgaging the property to the extent of $10,000, and also for the purpose of selling the mine if deemed advisable, adjourned without taking definite action. Interest still centres in the recent find in the East Butte mine, which is said to be even more extensive than at first reported. On the 800-ft. level the vein has been cross-cut and at the point of intersection the orebody is 40 ft. wide and runs better than 10%. The report of the Copper Producers' Association for October showing a decrease of only a little over 900,000 lb. came as a great surprise to the mining people in this city, as it was expected from all reports of sales and continued curtailment, that the decrease would be fully equal to that of September.

General Mining News

ALASKA

(Special Correspondence.)—A renewal of operations is in progress at the Rush & Brown mine, Ketchikan district, and shipping will soon be under way after having been closed down for several years.——The Wakefield, Ickis & Powers property at McLean's Arm is being developed by Mr. Ickis. The ore-zone has widened and is thus far persistent in depth as well as in strike.——The It mine bunkers are blockaded with ore ready for transportation to the Tyee smelter.——Development at the Dean prospect, Karta bay, has opened a fine body of gold-copper ore.——The Lon De Van M. & M. Co. is in over 700 ft. with the cross-cut adit. The ore carries lead and zinc high in silver.——At Doloni some development is being done.——It is the intention of the managers to install at 10-stamp mill on the Valparaiso property early next spring.

Ketchikan, November 4.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The local management of the Little Miami Copper Co. has been instructed from the New York office to renew sinking of the inclined shaft on the Cole group of claims which was purchased from the Cole Development Co. last spring. The shaft is alreadv 400 ft. deep and has run through high-grade copper ore in a vein 35 ft. wide. Richard Fleming, of Globe, is general manager.——The management of the Superior & Boston Copper Co. is daily expecting that the north drift on the eighth level will open the Great Eastern vein. The ground in the face is much broken and the presence of copper stain indicates that an orebody is near.——The Arizona Commercial Copper Co. has been made defendant in a suit for $15,000 damages by the estate of Morty McGinley, a pumpman and former employee, who was killed in the Eureka shaft about one year ago. The plaintiff asserts negligence on the company's part in not having properly secured the pump which fell on the workman.——Churn-drilling on the property of the Inspiration Copper Co. indicates that the low-grade orebody is at least 3800 ft. long, 200 ft. thick, and varies from 300 to 1200 ft. in width. The contour of the ore is very irregular, so that an estimate of average width is difficult. The copper content is about 2%. Two drills are in operation, continuing the prospecting. The connection between the Joe Bush and Scorpion shafts has been completed, and with 100 ft. more of driving the Colorado shaft, 2500 ft. west of the Joe Bush, will be connected with the other two. In the 75-ton test-mill a series of experiments has been commenced to determine the adaptability of the ore to concentration. T. R. Drummond, the manager, is employing 200 men.——The Arizona-Colorado Copper Co. has 200 tons of ore averaging 4% copper in the dump. Ore extraction is continued on the eighth level. The cross-cut to the vein on the second level is cut 25 ft. and should reach ore within 5 ft. of the present face. John F. Shaw is manager.——The secretary of the Lost Gulch United Mines Co. is expected in Miami and shortly after his arrival it is probable the 10-stamp mill will be put in operation. The company has 70 tons of gold ore in the bins and about 450 tons in the dump. The vein is exposed for a long distance in the workings and affords plenty of stoping ground. Lack of water has delayed milling hitherto, but the management estimates that sufficient water for treating ore can be obtained as soon as the annual rains begin. J. T. Harrington is president and is in charge of the property.

Miami, November 12.

YUMA COUNTY

(Special Correspondence.)—Work is to be resumed on the Planet mine, near Bill Williams fork and 12 miles from its confluence with the Colorado river, in the northern part of the county. This mine was operated until recently by the General Development Co., which holds one-third of the outstanding stock in the company owning the property. The new work will be undertaken by the old company and will be devoted principally to developing the orebody on the 350-ft. level from the vertical shaft. This shaft is over 600 ft. in depth, but the lower levels are under water. The oxidized orebodies show a high coatent of copper.

Parker, November 12.

CALIFORNIA

EL DORADO COUNTY

(Special Correspondence.)—Developments at the Good Luck mine are progressing vigorously. The south shaft is 160 ft. deep and is connected at the 60-ft. point with the north shaft, which is down 60 ft. The vein is tapped at a depth of 106 ft. by an adit. It is a well-defined ribbon vein, and has been opened about 400 ft. The mine is equipped with a 5-stamp mill, concentrators, compressor, and steam hoist. Eighteen men are employed. R. Mitchell is superintendent.——Operations have been resumed at the Vernon property, adjoining the Union mine, south of Placerville. It is said that a steam-hoist will be installed.——Developments have been commenced at the Leap Year.——Promising ore is being opened at the Encinal, and developments are going forward steadily.——San Francisco people recently took over the Starkey mine and have put men to work. There are a number of gold-bearing veins on the property which will be opened.——At the Stillwagon the mill is running on rich ore.——Work has been resumed at the Independence.——A full crew has been put on at the Lady Edner and Borealis group. If developments justify, the owner plans to install a milling plant early next year.

Placerville, November 11.

INYO COUNTY

(Special Correspondence.)—The Skidoo Mines Co., operating on the southwestern slope of Tucki mountain, Panamint range, recently shipped gold bullion to the value of $10,660, the result of operations during the last 15 days of October. This represented 780 tons of ore, the average recovery per ton having been $13.66. In addition, about $2.50 per ton is being recovered from the tailing, bringing the recovery to $16.10 per ton. Less than four hours was lost in mill work during the 15 days. Fifty men are employed in mine and mill, and from 40 to 50 tons of ore are being mined per day.

Skidoo, November 10.

SHASTA COUNTY

(Special Correspondence.)—The Balaklala Copper Co. has 35 miners at work in the Balaklala mines, and will increase the force. The Cottrell fume-controller is proving satisfactory and two furnaces will soon be in operation. The company is handling custom ore from the Bully Hill copper mines and numerous silicious gold ore producers.——At the Afterthought 18 men are working. Retimbering of the workings is going ahead, and considerable development being done. The charges against the management in St. Louis have not, thus far, affected work at the mine.——It is rumored that the Mammoth Copper Co. may install a Cottrell fume-controller at Kennett.——The Shasta Copper & Gold Co. has a small force on development. It is expected shipments will commence as soon as the company has perfected its patents.——Promising deposits of copper ore have been found at the Kent property, and a small crew is pushing development.——At the Vulcan good ore is being developed.——The Monarch is about to enter the shipping list. Over 100 tons of $24 ore will be sent out shortly. The ore carries gold, but shows little copper.——A small force has been put to work in the Uncle Sam mine. An attempt will be made to find a rich shoot which is believed to exist near the main workings.——At the Clipper fair-grade ore is being opened.——A number of small gold mines are showing renewed activity with the resumption of work at the Coram and Kennett smelters.——The mills of the Midas and Victor companies narrowly escaped destruction in the fire which swept Harrison Gulch November 6.——The Noble Electric Steel Co. expects

to resume the production of pig iron at its Heroult plant as soon as the Northern California Power Co. completes the enlargement of power facilities.

Redding, November 11.

SIERRA COUNTY

(Special Correspondence.)—At the mines that will be run during winter, work is being rushed to get everything in shape. Three 10-horse freight teams are making weekly trips with freight from Truckee in addition to the regular freighting outfits. The Sierra Buttes mines are installing a 10-drill Ingersoll-Rand compressor below the upper mill. The air-pipe is laid into No. 6 adit where extensive stoping and development are to be done. A winze is being sunk on the pay-shoot in No. 6, and a hoist is to be installed. The air-drills will be running by December 1. Ten stamps of the upper mill are dropping on ore taken out in development. Jay C. Folsom is superintendent.——S. J. Van Seyckel has given up his bond on the Hayes Consolidated, two miles south of Sierra City, and has taken a lease and option on the old Keystone mine adjoining the Hayes mine. The main adit is being driven ahead by machine-drills. The power-house and equipment have been overhauled and two shifts are working in the face. Ten men are employed, and William Barker is superintendent.——The 10-stamp mill of the Clipper is running with two shifts, and another shift will be put on. The mine has been opened by development and stoping is in progress. L. W. Holley is superintendent.——Richard Phelan of San Francisco has had men working on the water-rights and on the lower adit of the Butte Saddle mine. He has just sold the mine to George W. Aldrich and associates of New Jersey, who will take control and put on a large crew. The lower adit will be driven to cut the vein and the tramway repaired. ——The lower tunnel at the Colombo is in over 300 ft. and is in the lode formation. It is expected to reach the vein in another 40 ft. The new boarding-house and blacksmith-shop have been completed. C. R. Thompson is manager and John Thomas foreman.——The Primrose mine in Hog canyon, owned by Du Ray Smith, has been closed down for the winter.——C. R. Thompson, who has a bond on the Monarch mine in Ladies canyon, has closed down that mine and discontinued all work on the property.——The Trompetto Bros., of Sierra City, are developing a rich vein on their property northeast of Sierra City.——Many engineers and investors have been making examinations of mines in this vicinity the past month and the outlook for the camp is bright.

Sierra City, November 9.

TRINITY COUNTY

(Special Correspondence.)—D. F. MacDonald of the U. S. Geological Survey is investigating the geological features of the Headlight and other mines of this district.——Rose & Chapman have opened and are developing a 10-in. vein of gold-telluride ore in the Coffee Creek district.——Henry Carter, Joe Fifer, and John Mackay have taken a sublease on the Dorieska.——Jack Lytle and Bert Haskins have taken a three-year lease on the Patrick Holland hydraulic mine on the east fork of Coffee creek.——Anton Larson and Albert Anderson, former lessees of the Altoona cinnabar mine, have a cinnabar prospect two miles north of the Altoona on Crow creek, a tributary of the east fork of Trinity river, showing a 12-in. vein. They are making preparations to drive a 150-ft. adit to develop the vein.——Angelo Belli & Sons, who are operating on the Scorpion, a tributary of Trinity river, recently took out gold from two pockets on their Young group that exceeded $5000 in value. The pockets were 20 ft. apart and were found in a 10-ft. quartz vein running between porphyry and serpentine, and carrying abundant sulphides. Some high-grade ore was also taken from the veins. The Bellis will move their 5-stamp mill to the new mine in the spring.

Carrville, November 15.

TUOLUMNE COUNTY

(Special Correspondence.)—At the property of the United Mines Corporation, situated two miles northeast of Tuolumne, and comprising the Dead Horse, Eureka, Lady Washington, Grizzly, New Albany, and other claims of less note, underground operations are confined to the New Albany mine. On the 700-ft. level a winze has been sunk 200 ft., from the bottom of which drifts are being driven north and south. The north drift is expected to open a shoot of high-grade ore within 50 ft. from the point of beginning. The one to the south, which is now 30 ft. long, will be driven an additional 120 ft., where it will intersect a cross-fissure which in the upper levels has invariably been accompanied by high-grade ore. The winze will be sunk 200 ft. deeper. Both drifts and the winze are in medium-grade ore 12 ft. wide, with occasional rich spots. The mill is operated one shift on ore extracted in development, but preparation are being made by the superintendent, J. M. Elmer, to begin stoping to keep the mill running night and day. The plant consists of 20 stamps and two Hardinge conical tube-mills, and has a capacity of 120 tons daily, a 6-mesh screen being used. Amalgamating is done in the batteries and in the tube-mills. Tailing assays show that only 40c. per ton is lost. The crew at present numbers 36 men.——A large amount of development work has been done at the Rising Sun, near Arastraville, during

New Albany Mine and Mill, Near Tuolumne.

the present year, and it is the intention to start the mill in the near future. It is expected that the body of rich ore found on level No. 1 will be opened before long on No. 2 level, which is 300 ft. below surface.——The mill at the Wickham mine has been started by the bondholders to make a test run. If the test shows satisfactory results, work on a large scale will be commenced forthwith. The development thus far consists of a cross-cut adit which reaches the vein 100 ft. below surface and two drifts, each being 100 ft. long. The property is owned by W. P. Huston and is situated near the Rawhide.——It is expected that the bed of gravel toward which an adit is being driven at the Leap Year mine, southwest of Jamestown, will be opened within a few days. Work is in progress night and day, eight men being employed.——J. L. Witney, of Los Angeles, has taken a bond on the Water Lily mine, near Bostick Bar, on the Stanislaus river.——The old Buchanan mine, four miles southeast of Tuolumne, which has not been worked since 1893, has been bonded and will be reopened.——It is reported that work is shortly to be resumed at the Santa Ysabel, near Stent, in which B. C. Austin and J. S. Bagg, of San Francisco, are interested. ——The Ida Klein mine, near Stent, under bond to the company operating the Mazeppa, of which Louis H. Bedding is manager, is to be worked on a larger and more practical scale. The result of the mill test recently made was equal to expectations, and it has been decided to buy a 20-stamp mill. It is understood that a substantial payment has been made on the property.

Tuolumne, November 11.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The deal for the transfer of the Santiago mine in East Argentine district may be consummated the coming week, after which the property is to be turned over to the North American M. & S. Co., the consideration to be $500,000.——Work will begin this week

on the development of the Ramsdell property on Lincoln mountain. The cross-cut is to be driven 300 ft. farther, to intersect the series of veins, the first being the Golden Jack, said to be 40 ft. wide.——Good headway is being made in opening the McKinley property. The workings have been cleaned out and retimbered.——Since work was begun at the Vidler adit two months ago the big bore has been advanced 250 ft.——A streak of ore 3 in. wide has just been opened in the east drift of the Aetna vein, samples running as high as $400 per ton in gold and silver. Mr. Brady, the manager, has increased his force of miners. Shipments of smelting ore are being made, the average value being $60 per ton in gold and silver.——Ira Clapper, working a lease below the 240-ft. level of the Astor, has opened a 10-in. streak of smelting ore, assays of which show 350 oz. silver per ton. Some shipments are to be made.——Work was started last week in the development of the Spanish group situated on Columbia mountain. An adit is to be driven 100 ft. to cut under the upper workings where rich ore was mined a number of years ago.

Georgetown, November 10.

GILPIN COUNTY

(Special Correspondence.)—Five feet of solid ore is exposed on the west 13th level of the Topeka mine, in the Russell district. The streak of smelting ore is from 10 to 16 in. wide and runs 3.85 oz. gold per ton. H. P. Lowe is manager.——The Golden Slipper mine on Boulder creek is to become a shipper of ore from a 22-in. vein.——The Federal mine in Russell district has a body of mill ore 4 ft. wide. A shipment of 70 tons was sent to the Iron City mill last week.——Henry Baer has opened a 14-in. streak of ore on the St. Helena property that contains free gold.——Robert Davis, a lessee on the Topeka mine, is shipping ore that is said to sample 2.60 oz. gold per ton.——The 250-ton concentrating mill for the Topeka will be ready to operate within the next 30 days. In the meantime ore is being blocked.

Central City, November 10.

KANSAS

CHEROKEE COUNTY

(Special Correspondence.)—The Eureka company, representing one of the deepest developments in the district, is adding the output from the old Helen Hunt shaft on the land to the ore from the Eureka shaft, which is taken from 290 ft. and is found in a soft limestone and is difficult to separate from the ore. The ore from the Helen Hunt is from 150 ft. and is found in a hard flint matrix. It is the purpose to treat these two ores together, as they work to better advantage in this manner. A tramway is being built from the Helen Hunt shaft to the Eureka mill. A new shaft will be sunk on this lease. The mine will henceforth be under the management of R. E. Baines.——The draining of the old Southside tract under the management of Franklin Playter has been successful and the upper workings can now be entered. This land was one of the early-day bonanzas, and there is still a large amount of ore in the shallow workings, as well as in the lower levels where it has scarcely been touched. The large number of shallow holes and drifts formed reservoirs to hold the water, most of the old shafts being filled to the surface. It was necessary in places to cut drifts to isolated workings to drain these portions of the ground. Many sub-lessees are now at work. In addition to the work on the Southside tract, Mr. Playter has taken over the Cornwall and Palmetto tracts and has put them in order for production. He has remodeled the old Good Eye mill and will use it for a tailing plant for the Good Eye lease and others in the vicinity. A trial run resulted in the recovery of 2% ore. There is enough tailing in sight to last for two years. Development has been generally confined to above the 100-ft. level.——Members of the Mess Mining Co. have been inspecting their holdings. The mine has been in operation for several weeks, making large turn-ins. Mr. Savage, the manager, is also interested in the Quebradillas where a rich discovery of lead and zinc ore was made. The company is sinking from 63 to 190 ft., at which level a richer run has been discovered.——An Eastern company has installed a centrifugal pump for draining the Harvey tract and will make an effort to unwater the ground to 93 ft., where a 20-ft. run of ore is reported to have been found. Previous attempts to drain this land have not met with success.

MISSOURI

JASPER COUNTY

(Special Correspondence.)—There is much prospecting throughout the district. Particularly is this true in several of the camps on the outskirts, the Neck City field to the far north being especially important. Many successful capitalists from older fields have taken leases in this camp and are sparing neither expense nor effort to develop leases in this part of the field. They have been attracted by the remarkable finds and developments on the Quick Seven, Little Mary, and other tracts. The ore in this camp is unusually high grade. No camp ever opened in this district surpasses this for the length of time of operation. Among the newcomers are the American company, Ball & Gunning, Chapman & Lennan, C. E. Matthews, B. H. Van Hoose, and others, all of whom have been successful in the older fields, particularly the north Webb City sheet field. The ore in the Neck City camp is of the soft-ground formation, and as the ore is rich and at comparatively shallow levels, and only a beginning has so far been made, great things are expected from this camp.——The Thoms Station camp, north of Joplin, is another field where operators are busy and where some rich finds have been made. ——J. M. Short, who has been prospecting the past summer and who has made many discoveries, has recently opened a new field on the Brinkerhoff land. The company is known as the Sitting Bull company and has found ore in nine holes, the first stratum being lead at 154 ft., and zincblende at 170 ft. which continued to 185 ft. A shaft is being sunk on one of the drill-holes which verifies the earlier record. ——The Federated, one of the most successful companies in the district, also has a lease in this vicinity, and it is the plan to drill the 40-acre tract of the Mexico-Joplin land. Two holes are down so far, ore being found from 128 to 160 ft. Below this there was rock for a few feet, when a second run almost 50 ft. thick was penetrated. The cuttings run from 3 to 24% zinc, with a small amount of lead. There is an old shaft on the lease down 130 ft., being 2 ft. into the ore deposit. This shaft will be deepened. Equipment is being placed for this work.——In the Carl Junction field, Charles Wells & Bros. have found ore on the Chitwood farm showing 60 ft. of lead and zinc, the ore being cut at 170 ft. Estimates of the drill clippings show 8 to 12% ore. The ore was found in four out of five holes, being at practically the same level and varying from 19 to 60 ft. in thickness. The 40-acre tract will be tested by 17 more holes. The ore is in hard ground, resembling sheet or disseminated formation. This farm, though in the mineral belt, is virgin, and from its situation and proximity to other producers, is promising.——Another camp which has been practically idle for some time and which is again coming to the front is the old Midway field northeast of Joplin. Here an effort is being made to drain the old Osyka lease by Dexter and Shirley. It was on this tract that Watkins and others made a successful fight against heavy water with a centrifugal pump, proving for the first time the efficiency of this type of pump for this district. It has since been in general use throughout the region. This camp is unusually difficult to drain owing to the nearness of the mines to Turkey creek, which overflows and floods the workings in wet weather. A steam-pump is employed at present and the water is being slowly drained and preparations made to reopen the old tract on the upper levels. When the ground is unwatered it will be possible for adjoining companies to go to work, among which are the Brattleboro, the Kalitan, Green Dog, Billy Sunday, and others. There is a 200-ton mill on the Kalitan lease and the ore occurs at shallow depth where the ground is soft and requires heavy timbering.——Another old camp rejuvenated is the John Jackson tract in Chit-

wood, one of the early famous bonanzas. The mine was thought to be exhausted, and abandoned years ago. Recently the St. Louis-Joplin company took over the land, and since that time the company and lessees have been prospecting and opening promising deposits. A mill has been moved from Zincite and rebuilt at the old John Jackson site. The ground is well opened and a face of ore available where ten machines could be set to work. The faces of ore are high and the dirt rich. In addition to this mill the A. B. C. mine on the same land is beginning the taking up of a 27-ft. stope below the 30-ft. face of ore already worked. Solid rich ore in large chunks has been taken out. The sinking of this shaft to a deeper level was difficult, owing to the inrush of water. Besides these two properties others have been opened on the John Jackson tract. There is a large amount of prospecting going on northwest of the Wilcox where the drill entered ore at 160 ft., continuing to 205. The cuttings are estimated to run 10%.——To the south of Joplin on the Matthes Bros. land there are several new mills. One is the 250-ton plant of the Jackson L. & Z. Co. which was removed from the South Webb City field.——In the same part of the field in Gordon Hollow there are two new mills, one built by the Niagara Falls company on a lease of the C. C. Playter land, which will make its initial turn-in this week. It is a 200-ton plant driven by gas-engine. One difficulty met is the scarcity of water. Pumps have been placed in two shafts and a pump line built to the old Puritan deep well to furnish a water supply. The ore is found at 80 ft. in two shafts and the dirt is said to run 7% zinc, with some lead.——Another new producer in the same part of the field is the Black Jack, named from the peculiar blackness of the ore which resembles lead ore. The ore from this mine, as well as others on the land, is cleaned at the Latshaw custom plant. Operations at present are conducted above 80 ft. and a face 17 ft. high is carried. Below this a larger body of ore has been discovered which is of lower grade and requires a mill before it can be treated profitably.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—Earnings which would permit the payment of a dividend of $15,000 per month are being made by the Cumberland mine and cyanide plant at Maiden, according to James Breen, chief owner. The second unit of the mill has been in operation a month, 200 tons per day now being treated. Mr. Breen, speaking of the mill work, states that up to the end of September the heads had been running over $10 per ton, though they had not been breaking the full width of the vein. Beginning with October, the plan was to mine all ore running as high as $2.50 per ton, which will bring the heads down to about $6. The cost of mining and milling is said to be $2 per ton, and the extraction is claimed to exceed 90% of the assay value.

Maiden, November 10.

(Special Correspondence.)—The Kendall Gold Mining Co., operating at Kendall, has paid its seventy-first dividend of $10,000. This is the second dividend recently, a like amount having been distributed on September 22. The total of dividends paid to date is $1,305,000. The Kendall mine has run steadily since its mill went into operation 15 years ago. Finch & Campbell, of Spokane, own the controlling interest.

Kendall, November 12.

NEVADA

NYE COUNTY

(Special Correspondence.)—Since the automatic sampling machinery was installed at Eclipse mill six or seven lots of ore of about a carload each have been treated for local lessees. With one exception these lots ran from $20.40 to $35.80 per ton. The resumption of operations at this mill as a custom plant has stimulated work by local lessees.——The last ore at the Leland mill was run through on November 8. The ore came from the Hayseed mine at Lee, California. The last week's run at the mill was successful, although the exact amount of the clean-up is not yet known. The saving by amalgamation from this ore is from 75 to 80%. This mill is built on flat ground about three-fourths of a mile from Leland station on the T. & T. railway, and consists of three 1350-lb. Nissen stamps. Water for it is pumped from a nearby well 100 ft. deep. Part of the water from the battery is saved and returned to it by a water-wheel, which also elevates some of the tailing. Ore hauled in wagons is dropped through a grizzly to an underground bin from which it is hoisted in a skip to the mill bin by a Fairbanks distillate hoist, the engine of which furnishes the power for the mill.——The remodeled Wolftone mill at Manhattan resumed work a few days ago with full force.

Rhyolite, November 10.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—At the El Paso fair the judges awarded the Mogollon exhibit first premium for display of gold and silver ores, and a diploma was given the Mogollon Gold & Copper Co. for gold-silver-copper ores.——Good progress is being made in sinking the main shaft at the Socorro mine. Development on the new orebody found in 500 East continues in good milling ore, of which 3600 tons was milled during the month. The use of air-drills was discontinued November 4, hand steel now being employed. Regular shipments of bullion and concentrate are being made.——At the Deadwood mines another vein 5 ft. wide carrying ore was cut in sinking sump below the 500-ft. level. This is on the foot-wall side of the Last Chance vein, which was passed through just below the 400-ft. level. In all, four well-defined veins have been cut in sinking the vertical shaft to the present depth. The oil engine, tables, and other machinery for the mill have reached Silver City; also the pipe for the water line. Rapid construction of the mill continues.——The last clean-up of the Ernestine M. Co. produced 11,495 troy ounces of bullion; 48 sacks of high-grade concentrate was obtained from 562 tons of ore crushed the past week. The recently installed pipe-line is furnishing ample water for the plant, by gravity, effecting a great saving over the old system of pumping. Thirty stamps are now dropping. On November 1 a night shift was put on in the mine and work is being pushed at a number of headings, all of which are reported in ore.——The Treasure Mining & Reduction Co. is taking milling ore from two of the old stopes.

Mogollon, November 11.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The Standard mine, formerly known as the Grady group, between Silverton and New Denver, bought for $30,000 three years ago by John A. Finch, of Spokane, and George Ayland, of New Denver, has shipped ore worth $200,000, mostly during the period of development. The ore so far shipped has netted the owners $50 per ton, its content being from 65 to 70% lead and 80 to 100 oz. silver per ton.

New Denver, November 10.

(Special Correspondence.)—Shipments from the Granby mines showed a further increase for the past week, even though the ore from the 300-ft. level is being dropped into a pocket and hoisted through the Victoria shaft. A new tunnel is now being sunk, however, which will replace outlet No. 3, recently destroyed by fire. The new adit will probably be equipped with a crusher and a conveyor for loading cars at the Great Northern tracks. Machinery in the new shop was started up last week. This company has sent men to the Hidden Creek mine, on Observatory inlet, where development and diamond-drill work are to be started. Three diamond-drills and some rock-drills will be operated until spring.——Work has been resumed on the Greenwood-Phoenix adit with 15 men. Two 3¼-in. drills are being operated.——Development has been in progress on the Maple Leaf group at Franklin camp the past summer, and the work will be resumed next spring.——Work on the 15-ft. seam of coal now being carried on by the Osoyoos Coal Co., at Princeton, has exposed the seam for 310 ft. An entry has been driven on the seam for 100 ft. Three car-

loads of coal are ready for shipment which will be moved as soon as snow roads are in good condition.——Shipments of ore from the Boundary district for the week ended November 5 were: Granby mines, 18,546 tons; other mines, 12,479 tons; total for the year, 1,410,256 tons.

Phoenix, November 10.

(Special Correspondence.)—On the Perrier group south of Nelson an air-compressor is to be installed. The vein being opened is 2 ft. wide. A shipment of 10 tons to the smelter averaged $45 per ton. Alfred Crossley, of Nelson, is manager.——The vein on the King George V, on Bird creek, has widened to 3 ft. Assays of ore taken from the main vein have shown from $10 to $95 per ton in gold, mostly free milling.——The adit on the Dundee mine at Ymir has been driven nearly 400 ft. This adit must be driven 2300 ft. to cut the vein. This will give 1000 ft. of depth on the vein and will drain the workings.——At Moyie new orebodies have been opened at the St. Eugene mine of the Consolidated company. Work is being done on the Aurora and Society Girl mines there and regular shipments will be made this winter.——A carload of horses was taken to the Rambler-Cariboo mine last week, some of which are to be used in hauling ore from the mine to Three Forks during the winter.——At Sandon a body of ore has been opened on the Ruth. The Richmond-Eureka and Slocan Star are shipping and doing much development. The Noble Five, Panama, Idaho, Enterprise, and Hewitt are all making good showings, while the larger properties like the Van-Roi, Standard, Lucky Jim, and Rambler-Cariboo are all making substantial additions to plant and preparing for a busy winter.——The ore and concentrate shipments from the Nelson-Slocan district for the week ended November 5 were 5360 tons, and for the year 257,277 tons.

Rossland, November 10.

W. Fleet Robinson, the provincial mineralogist for British Columbia, has just recently returned to the city of Victoria, from an official visit to Portland canal, where he examined a number of mineral claims in the new mining camp situated in the vicinity of the canal. Pending the issue of an official bulletin, his conclusions are, briefly, that there is as yet only one property in the camp tributary to Stewart, the town at the head of the canal, that may reasonably be regarded as a mine, namely, that of the Portland Canal Mining Co., of Victoria. This company has been developing two of its group of eight claims for three years, and recently completed the equipment of the first 75-ton unit of its concentrator. Ore is conveyed by aerial tramway from the mine to the concentrator and a concentration of about 3½ into 1 is being made. The plant was found to be doing excellent work, making an exceptionally clean separation. While the average value of the ore is low, it is considered satisfactory and should leave a fair margin of profit. There is a large quantity of ore blocked out and a still larger quantity practically assured. Much prospecting is being done throughout the district, but no other property than that above mentioned is yet in a position to ship ore on a commercial basis, nor likely to be until next year. Many claim-holders, however, are endeavoring to ascertain the worth of their respective properties. It may be added that the Portland Canal Mining Co. expects to ship at least 1000 tons of concentrate before the close of this year, probably early in December, and arrangements are being made for its transportation and reduction.——Reliable information concerning a new mining field at Steamboat mountain has been received in Vancouver from time to time during the last three months. Mineral claims have been staked there and in the surrounding country, and assays from specimens of ore from some of these are reported to have given returns ranging from $15 to $200 per ton. The new camp has not yet been visited by either Dominion or Provincial officials of the respective departments of mines, so no authoritative information as to its merits has yet been made. From men who have looked it over it has been learned that the formation is andesite, with intrusive sheets of quartz-porphyry, and that free gold can sometimes be seen in the latter. The field is distant about 40 miles from Hope, on Fraser river. It is in the vicinity of Skagit river, which flows south from the Hope mountains into the State of Washington. Hope is in Yale mining division, a small subdivision of the large Yale district, which embraces a considerable area of territory in central southern British Columbia. From Vancouver, B. C., to Hope, by the Canadian Pacific railway, the distance is 89 miles; the route thence to Steamboat mountain is by the Sumallow river trail and then down the Skagit. The new field is comparatively easy of access, but now that snow has fallen no effective surface prospecting will be practicable until next spring. Meanwhile several properties have been sold by the locators, and preparations are being made for developing them next season.

ONTARIO

(Special Correspondence.)—E. A. Wallberg, president of the Mines Power Co. (Ltd.), of Cobalt, says he will continue without loss of time the building of the Porcupine railroad. He expects to have cars running over 10 or 15 miles of line this winter. The remaining distance will be completed in the spring. The plan is to use steam this winter and as soon as the power plant can be completed next summer electricity will replace steam.

Porcupine, November 12.

(Special Correspondence.)—The six Herlehy-McPharland claims in lot 5, consessions 2 and 3, Tisdale, in Porcupine district, recently sold to E. V. Perkins, have been taken over by a syndicate of New York capitalists. A company is being incorporated to develop this property and a large force of men will be put to work at the mine. Assessment work on this property has opened seven veins, one of which is 8 ft. in width and pans gold freely. The Herlehy-McPharland group is in the heart of the richest section of the Porcupine area, about midway between the Rea and the Dome mines. The Rea Mines Co. is controlled by the Consolidated Gold Fields of South Africa, and the Dome Mines Co. by interests affiliated with the International Nickel Company.

MEXICO

CHIHUAHUA

(Special Correspondence.)—The October production of the Rio Plata Mining Co. amounted to 83,000 oz. silver, besides a large amount of concentrate.

Chihuahua, November 12.

VERA CRUZ

(Special Correspondence.)—The Huasteca Petroleum Co., which recently completed a pipe-line from Casiano to Tampico, is pushing the work of providing storage facilities for its product, both at Tampico and along the pipe-line. In addition to three large steel tanks, a 300,000 bbl. concrete reservoir will be built at Casiano. At San Geronomo, the first pump station north of Casiano, a concrete reservoir of 500,000 bbl. capacity will be built. In addition to the seven 55,000-bbl. tanks at the Tampico terminal, a million-barrel reservoir will be built. The pipe-line has a capacity of 26,400 bbl. per day. The pipe is 8-in. smooth bore and has been tested to 1200 lb. per square inch. The company has laid a cable across the Panuco river from Tampico. It is intended to extend the pipe-line across the river, thus connecting the terminus on the south side of the river with the railroad terminus on the north side. The bulk of the output of the company is taken by the Mexican Central railway, the Mexico National Gas Co., of Mexico City, and the Waters-Pierce Oil Co. A contract was recently entered into with the last named company for the supply of 2,500,000 bbl. of oil within the next five years, the price being 92½c. per barrel.

Tampico, November 10.

ZACATECAS

(Special Correspondence.)—Volney D. Williamson, of Spokane, has gone to New York to negotiate with the Exploration Company, Ltd., of London, for the sale of two mines in the State of Zacatecas, which were acquired years ago by the late V. M. Clement and Mr. Williamson.

Zacatecas, November 12.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

MINERS ASSUMPTION OF RISK

A driver in a coal mine does not assume the risk of injury due to the failure of a mine boss or mine operator to perform the statutory duty of making a dangerous place safe, where the statute clothes the mine boss with authority to exclude miners from any dangerous place in the mine until it is made safe; and such a driver in a coal mine does not assume the risk of injury, where the mine boss directs him to enter the place after it has been made safe, but by which he was in fact injured. The doctrine of assumed risk does not apply merely because the manner of making the place safe is left to the discretion of the mine owner and the judgment of the mine boss.

Princeton Coal Mining Co. *v.* Howell, (Ind.) 92 Northeastern 122. June, 1910.

STATUTE REGULATING SPRINKLING AND VENTILATING MINES

The statute of Indiana (Burns' Ann. St. 1908, section 8579) provides that roadways or entries in any mine shall be regularly and thoroughly sprinkled when they are so dry that the air becomes charged with dust; and it is made the duty of the mine inspector to see that the provision is complied with. The fact that this provision is a part of the same section in which provision is made for ventilating mine in no wise abrogates the duty to sprinkle, irrespective of the subject of ventilation, and was imposed for the benefit and protection of persons employed in the mine. A failure of the mine operator to so sprinkle the roadway and entries when so filled with dust, and from which a dust explosion resulted, injuring a miner, as required by the statutes was negligence on the part of the owner or operator and entitled the injured miner to recovery. The failure to sprinkle may be charged as the proximate and direct cause of the explosion and the injury of the miner. The dust in such case would be regarded as the efficient or proximate cause of the explosion and injury.

Vandalia Coal Co. *v.* Yemm, (Ind.) 92 Northeastern 49. June, 1910.

INJURY TO MINER—MEASURE OF DAMAGES.

In an action for damages to a miner, worldly condition of the parties, such as poverty or riches, whether possessed of property, whether industrious, whether married or single, or having a family, or a large or small family, the number and ages of the family, standing of the parties in the community, and whether anyone is dependent on such injured miner for support, cannot be proved, as this and similar conditions are too likely to arouse the sympathy of jurors to a degree beyond award of compensation; but evidence as to the occupation and compensation, and that the injured party is not able to follow his usual occupation, does not fall within this rule. The elements of mental anguish cannot be specialized or calculated and hence must be left to the sound discretion of the jury; but the damages awarded must be those arising from pecuniary loss, in which physical condition and earning capacity at the time of the injury, and the effect of the injury upon such capacity, are necessarily involved, together with physical pain and mental anguish arising from the injury inflicted and expenses incurred in treatment, nursing, etc.; mental anguish arising from apprehension cannot be considered. Where it was shown that the miner was badly burned about his hand, head, and body; that he was injured internally by inhaling the gases, smoke, and dust; that he was permanently injured; that he suffered and continued to suffer great bodily pain and mental anguish; that he was unable to work for a period of many months, during which time he could have earned $5 or $6 per day and where he had expended $200 for medicine and for medical aid and nursing, a judgment for $10,000 was not excessive.

Vandalia Coal Co. *v.* Yemm, (Ind.) 92 Northeastern 49. June, 1910.

Recent Publications

Annual Report of the State Geologist of New Jersey. for 1909. By H. B. Kümmel. Pp. 123. Index. Trenton. 1910. Treats largely of the State water supply.

Production of Monazite and Zircon in 1909. By Douglas B. Sterrett. U. S. Geol. Surv.; advance chapter Mineral Resources, 1909. Pp. 11. Washington, 1910.

Analyses of Ores. Non-metallic Minerals and Fuels. Report of Chemical Laboratories, Department of Mines, Canada. By F. G. Wait. Pp. 126. Ottawa, Canada, 1910.

Wood-Using Industries of North Carolina. By Roger E. Simmons. North Carolina Geol. Surv. Pp. 74. Ill. Raleigh, 1910. Deals with timber supply of the State, its uses and conservation.

Gypsum Deposits of New York. By D. H. Newland. Education Department, Bulletin No. 43, New York State Museum Pp. 94, Ill., maps, index. Albany, 1910. Describes history, occurrences, geology, and uses of gypsum.

The Friar-Land Inquiry, Philippine Government. By W. C. Forbes, D. C. Worcester, and F. W. Carpenter. Pp. 208. Manila, 1910. Relates to the official inquiry into the administration and sale of friar lands by the Philippine Government.

Mineral Resources of the Philippine Islands. By Warren D. Smith, issued by the Division of Geology and Mines, Bureau of Science. Pp. 81. Ill. Manila, 1910. Describes mineral districts and some individual mines, and running methods.

Monografias Mineras i Metalurjicas. By F. A. Sundt. Pp. 217. Ill. This volume in Spanish gives a comprehensive account of the present condition of the mineral industry in Chile. Issued under the auspices of the National Mineral Society, Santiago, Chile.

Volatile Matter in Coal. By H. C. Porter and F. K. Ovitz. Bull. 1, U. S. Bureau of Mines. Pp. 55, Ill. Washington, 1910. This, the initial bulletin of the new Bureau, includes a scholarly account of experimental work on a matter of large practical importance.

Nineteenth Annual Report, Bureau of Mines, Ontario. By F. Cochran, Minister of Mines. Pp. 245. Index. Ill. with maps. Ottawa, 1910. Contains the usual report of the condition of the mining industry in the Province of Ontario, with description of new camp of Porcupine.

Granites of the Southeastern Atlantic States. By T. L. Watson. U. S. Geol. Surv. Bull. 426. Pp. 282. Index, map, and Ill. Washington, 1910. This work treats exhaustively of the occurrence of granite and similar rocks suitable for structural purposes. Many quarries are described together with the character of the rock obtained.

Recent Advances in Construction of Electric Furnaces. Bull. 3. Department of Mines, Canada. By Eugene Haanel. Pp. 76. Ill. Ottawa, Canada, 1910. Describes the various types of electric furnace used in the smelting of iron ore and the manufacture of steel; also in the reduction of spelter and zinc oxide. It contains a number of detailed drawings.

Gold Dredging in California. By W. B. Winston and Charles Janin. Bull. 57, California State Mining Bureau. Pp. 32, Ill., maps, index. San Francisco, 1910. This is an excellent report covering the statistics and technology of the dredging industry. It is lacking in that the discussion of the geology of the dredging fields is disappointingly brief and is quite inadequate to the purposes of an engineer who desires to learn where to look for other dredging fields. However, where there is so much that is good, it would be but caviling to emphasize the defects. As to the conditions under which the engineers worked who prepared the bulletin, see editorial comment.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. F. Bain is at Bakersfield.

E. B. Kirby is in San Francisco.

Ralph Arnold is in San Francisco.

J. R. Finlay was in San Francisco.

John B. Farish is in San Francisco.

Albert Burch has returned from Alaska.

C. H. Munro has returned from the North.

Bertram Hunt has gone to Mercur, Utah.

Arthur L. Pearse has returned to London.

George Otis Smith is visiting California oilfields.

E. A. Sperry is at Nicolaus, California, making surveys.

Walter W. Johnson has returned to San Francisco from Nome.

J. A. Cause, of Boise, Idaho, recently visited Parral, Mexico.

Dan Patten, of Calistoga, California, has been in San Francisco.

Alexander Imhoff has returned from Mexico and will reside in Los Angeles.

James A. Barr is in the Nashville hospital recovering from a slight operation.

J. Nelson Nevius has returned to Los Angeles from Oroville and Plumas county.

Roy H. Clarke recently returned to Spokane from the Altar district, Sonora, Mexico.

H. S. Walker has left the service of the Real del Monte company and is in Mexico City.

E. M. Ray, of Pittsburg, is inspecting various mines in the State of Chihuahua, Mexico.

S. E. Bretherton, who is in Sonora, Mexico, expects to return to San Francisco December 1.

Arnold S. Langley has left the service of the Britannia M. & S. Co. and is at Crofton, Vancouver Island, British Columbia.

H. P. Eells, president, with W. W. Coleman and E. K. Swigart, vice-presidents of The Bucyrus Co., are in San Francisco.

W. F. Harrison has resigned as manager for the Indé Gold M. Co., at Indé, Durango, Mexico. He is succeeded by R. McCart.

Edmund T. Perkins has resigned from the U. S. Reclamation Service and has opened an office at 1110 First National Bank building, Chicago.

G. A. Guess has resigned as smelter superintendent for the Tennessee Copper Co., and sails from New York about December 1 for Cerro de Pasco as metallurgical superintendent of that plant.

John V. N. Dorr, accompanied by his family, sails for England on the *Blucher*, from New York, on November 19. He will be abroad about a month. Mr. Dorr will make his London headquarters at the offices of *The Mining Magazine*, Salisbury House.

The San Francisco Section of the Mining and Metallurgical Society will give a subscription dinner in honor of George Otis Smith, director of the U. S. Geological Survey, at the Palace Hotel, November 22, at 6:30 p. m.

The Bureau of Mines has just sent one of its rescue cars to Chicago. From there the car will go to a number of Illinois mining towns before proceeding to Rock Springs, Wyoming. Sumner S. Smith is in charge, and will be assisted by a representative of the Red Cross. They will give demonstrations in the use of rescue apparatus and will take the preliminary steps looking toward the organization of rescue companies in all the mining towns of Illinois.

JEFFREY EXHIBIT AT THE WESTERN PENNSYLVANIA EXPOSITION

Thousands of visitors, including a large number of coal operators and mine superintendents, were afforded a novel treat in their visit to the Jeffrey exhibit of modern mining machinery, considered by every one who saw it, the feature at the Western Pennsylvania Mining Exposition. This exhibit, occupying a space 100 ft. in length by 30 ft. wide,

was situated in the northwestern corner of the Machinery hall. It was designed and built by the Jeffrey Manufacturing Co., Columbus, Ohio, being in the form of a model mine room, showing their latest and most improved types of mining machines, electric drills, as well as electric mine locomotives, in actual operation, practically as they would be operated in underground workings. This mine room had a coal face 45 ft. long by 6 ft. high, constructed of large lumps of bituminous coal. Practical demonstrations were daily conducted by the operators actually undercutting and drilling the coal and hauling same out of the room.

OCTOBER COPPER REVIEW

The Copper Producers' Association statement, issued November 10, shows a large decrease in stocks at the end of October as compared with September. The figures, in pounds, follow:

	Oct. 1910.	Sept. 1910.	Oct. 1909.
Stocks	148,793,714	168,881,245	151,472,772
Production	126,069,284	119,519,983	124,657,709
Totals	275,262,998	288,401,228	276,180,481
Domes. delivery	67,814,172	64,501,018	66,359,617
Exports	68,186,910	75,106,496	56,261,238
Total consumption	136,001,084	139,607,514	122,620,855
Stocks remaining	139,261,914	148,793,714	153,509,626

L. Vogelstein & Co. report the following figures of German consumption of foreign copper for the months January to September 1910:

	Tons.
Imports	129,440
Exports	6,938
Consumption	122,502

Of the above quantity, 111,131 tons were imported from the United States. Consumption during the same period in 1909 was 114,960 tons.

COMMERCIAL PARAGRAPHS

The Hendryx Cyanide Machinery Co. has installed at its testing plant at 107 William street, New York, a Merrill zinc dust press.

The Harbison-Walker Refractories Co., Pittsburg, Pa., announces that Kenneth Seaver has been appointed chief engineer of the company.

The Wood Drill Works, Paterson, New Jersey, has issued a special circular giving brief facts concerning the dimensions of the Panama Canal, and incidently a view of Wood rock drills at work on the Miraflores lock chamber.

Warren B. Lippincott and James M. McClave have formed a partnership under the name of Lippincott & McClave, with offices at 601 and 602 Ideal building, Denver, Colorado, where they will engage in practice as chemical and metallurgical engineers.

The Lane Slow Speed Chilian Mill Co., Los Angeles, reports sales of Lane mills to the following: Victory Gold Mining Co., Ophir, Montana; Liano Gold Mining Co., Llano, Texas; R. M. Wilson, Grants Pass, Oregon; Cia. Minera Zaragoza, Zacatecas, Mexico; Rodolfo Munoz, Guadalupe, Mexico; Unity Mining Co., Virginia City, Nevada.

CATALOGUES RECEIVED

Hendryx Cyanide Machinery Co., New York. Catalogue No. 7. Illustrated, 24 pages, 5½ by 8 inches.

The Cyclone Drill Co., Orrville, Ohio. General Catalogue A-50. 'Prospecting Machinery for Coal, Water, Oil, Gas, Mineral, and Placer Mining.' Illustrated. 128 pages. 7 by 10 inches.

The Stearns-Roger Mfg. Co., Denver. Catalogue 100, Section 127. 'The Edwards Mechanical Roasting and Chloridizing Furnaces, and the Edwards Ore Cooler.' Illustrated. 28 pages. 7¼ by 9 inches.

Falkenburg & Laucks, Seattle, Wash., booklet showing views of the laboratories and information concerning the assaying, testing, and inspection service rendered by this concern. Illustrated, 16 pages, 3½ by 6 inches.

The annual report of the Consolidated Mining & Smelting Co. of Canada for the year ended June 30, 1910, has just been issued. This company operates large mines at Rossland, Phoenix, and several other camps in British Columbia, with a smelter at Trail. The amount of ore treated at the smelter was 487,125 tons, returning a profit of $309,945.08. The ore treated yielded 137,614 oz. gold, 2,162,406 oz. silver, 42,368,816 lb. lead, and 5,974,959 lb. copper. Total value, $5,911,767. During the year two new properties were purchased—the Molly Gibson group, near Nelson, and Group No. 7 in Boundary district. Property and plant account shows an increase of $244,202.19.

The United States Civil Service Commission announces an examination on December 7, 1910, at all regular examination centres in the United States, to secure eligibles from which to make certification to fill vacancies as they may occur in the positions of mineral examiner in the Forest Service at $1800 per annum, and also in positions of surveyor for the inspection of mineral deposits under the Chief of the Field Divisions of the General Land Office, at $7 per diem. Candidates should at once ask for application and examination form 1800.

On Friday, November 4, 1910, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 158 of $81,750.

TABLE OF CONTENTS

EDITORIAL

UNREST continues in Mexico, as is evident from daily press despatches. There is little doubt, however, that the Government will deal firmly with the situation, promptly suppressing every revolutionary demonstration.

DIVIDENDS have been suspended by the Round Mountain Mining Company pending appeal to the Supreme Court of Nevada from the adverse decision in the District Court of Nye county, whereby the company has been held liable for $165,000. This mine, which has been remarkable for the richness of its ore and the ease with which it was milled, thus proves anew that in estimating cost of mining rich ore in America an engineer should never neglect to allow generously for litigation.

FIRE injured the top works at the Pittsburg mine last week, but did not destroy the plant. Mr. M. B. Kerr was fortunate in having an ample supply of water under pressure and with it was able to save most of the machinery and buildings. The Pittsburg is one of the old mines of Nevada county now being re-opened. The shaft had been pumped dry and sufficient development done to give assurance of good orebodies, so the plant will be rebuilt at once.

DISCOVERY of oil in the Bohemian well, south of Coalinga, California, is of unusual interest since, if the amount be important, the discovery will add several miles to the proved territory. The officers of the U. S. Geological Survey had estimated that the oil sand would be found at 3600 feet in depth, an estimate which proved almost exact. The oil is brown in color and is said to test 40° B. Until more work is done it will be impossible to say what the production will be, but it is thought that a good well has been found.

PORCUPINE is Canada's latest contribution to the mining camps of the world. On another page of this issue will be found an interesting description, by Mr. Reginald E. Hore, of the geology of the district, and of several of the more important vein outcrops. Judging from the description by Mr. Hore, the veins of Porcupine greatly resemble some of the Mother Lode of California, particularly those in Mariposa, Tuolumne, southern Calaveras county, in central Amador county near Jackson, and also at and near Placerville, El Dorado county. In these several localities there are huge masses of the carbonate of lime, magnesia, and iron, commonly known as ankerite, which are seamed with large and small veins of quartz, in much the same manner

as that described as occurring at Porcupine. In California these great masses of ankerite, some of which are over 300 feet wide, are usually accompanied by an abundance of the green micaceous mineral, mariposite. No mention of mariposite, or any mineral answering its description, is made by Mr. Hore. However, mariposite is sometimes absent in the California ankerite masses. Generally, the ankerite of the Mother Lode is auriferous, though not to a profitable extent. That in the Rawhide mine in Tuolumne county was an exception, some of it being extremely rich in gold.

SWANSEA and Vivian are names well known in metallurgy. It is interesting to note that according to the terms of the will of Mr. R. G. Vivian, who died last June, £40,000 is to be set aside to found and endow Glynn Vivian Miners' Missions, one each in the United Kingdom, France, Spain, Germany, Siberia, Russia, South Africa, and Chile. The list suggests the width of interest of the firm of Vivian & Sons. It is proposed to build halls "to be made comfortable and as attractive as possible with books, newspapers, and a supply of tea and coffee, so as to draw miners and other persons whom the halls are intended to benefit, away from the drinking bars." Many such attempts have been made, not always with great success. Such clubs, however, are to be encouraged even if they are not always appreciated. The purpose of the gift may be commended, as well as the spirit that led Mr. Vivian to try to make some return to the great industry from which he drew his wealth.

SUCCESS is attending the application of the Cottrell process to clearing the smelter smoke at the Coram plant of the Balaklala Consolidated Copper Company. This is the more notable since owing to the exigencies of the situation it was necessary to build the working plant with one hundred times the capacity of the experimental apparatus. This was a bold leap into the unknown, and it is not surprising that at first the big plant was not entirely successful. Many baffling difficulties were met, but now the apparatus is working steadily, clearing the smoke of 90 per cent of the solid matter. If the gases were discharged from several stacks instead of one, the smoke would not be dense enough to be noticed. It is evident that the remaining difficulties can be overcome, and a great step in metallurgical progress is to be shortly completed. We offer hearty congratulations to Mr. F. G. Cottrell, the inventor, and Mr. R. T. White, who as manager had the courage to install the apparatus on a working scale where failure would have been most disastrous.

PRESS DESPATCHES state that a six-inch bore-hole in the bottom of the El Paso shaft, on Beacon hill in the Cripple Creek district, Colorado, has reached the Roosevelt drainage adit. This bore-hole is draining the famous El Paso workings, the water being under control. The adit has advanced to a point very near the El Paso shaft and near the contact of the granite and the andesite, but whether the adit will be driven beyond the El Paso mine has not yet been determined. It is thought that a very wide area will be benefited by the drainage adit for the reason that the effect of pumping operations in the El Paso mine was noticeable in some of the deep mines near Goldfield. When pumping at the El Paso was suspended the water rose in the mine-workings two miles away, and when pumping was resumed the water level in these mines soon gave evidence of it, indicating that there was a direct connection between the district about the El Paso and the mines near Goldfield and Victor. Should the drainage adit prove to have a marked effect on the water level of these distant mines, in all probability the drainage project will not be advanced for some time, but if it does not have a beneficial effect, then the adit will doubtless be driven forward to drain the Portland, Vindicator, Golden Cycle, and other mines of that vicinity.

Oil on Public Land

In the California oilfields the situation as regards title to wells drilled on public land is thoroughly bad. Remedial legislation is needed at once, and in obtaining it the oilmen deserve and should have, the assistance of all right-thinking men. Through executive withdrawals, new legislation, and Land Office decisions, the operators have been placed in a most unexpected and embarrassing situation. The great Lake View well is on land that, according to present interpretation, cannot be patented, though it was located prior to withdrawal, and there can be no question either as to the discovery of oil or the good faith of the owners. Of the 169 companies operating in the Coalinga field it is estimated that 75, claiming 11,000 acres or more, are unable to proceed to patent, though they have collectively expended nearly two and a half million dollars in drilling and have brought in a large number of excellent wells. While these companies cannot obtain patent, neither can they stop drilling without losing what few rights remain to them. In many cases it is impossible to turn into cash the oil already produced, and with all these uncertainties it is naturally impossible to interest capital so as to continue the drilling required by the terms of the withdrawal law. To make a bad matter worse; it is rumored that the Post Office department is likely to proceed against all those companies that have been using the mails to sell stock, where the operations are being conducted on unpatented land. As a net result, production is being unnecessarily forced at the same time that men who have already invested are straining every resource to meet unexpected assessments.

In order to understand the situation it is necessary to recall that prior to the withdrawal of the oil lands many claims had been located by men who proceeded according to established custom and followed current court and Land Office interpretations. In entire good faith they obeyed the law as it was then known. There was no question of dummy entrymen, of agricultural or gypsum claims, or of any

other irregularity. When Congress passed the act validating the executive withdrawals, a clause was incorporated in the law to protect the equity of those who had previously entered lands and who had continued in good faith to develop the property. Shortly thereafter patents were refused on the ground that discovery had not been made prior to location and that transfer of title had occurred before issue of patent. These rulings, while well founded in law, were new and completely changed the conditions. Practically, the oilmen have now no assurance of title except belief in American fair play and justice. Under most trying conditions they are showing their own good faith, not only by continuing to 'diligently proceed with development', but by making a full and frank statement of their case. The region has recently been visited by Mr. Frank Pierce, Assistant Secretary of the Interior, and Mr. George Otis Smith, Director of the United States Geological Survey. They have been given every facility for learning the facts and seeing the exact situation. In addition, the oilmen have selected a strong committee to present their case at Washington. There will be many differences of opinion as to what legislation should be enacted to govern future development of oil on the public land, but there should be no differences as to the justice of giving prompt relief to those who in good faith have already risked their time and money following the law as it was interpreted at the time they began work.

Proposed Mining Method

In past years mining has seen many changes. The methods of today are in some respects entirely unlike those in common use during the greater part of the nineteenth century. The square-set system of sustaining the backs of stopes was introduced in 1860 on the Comstock Lode, in Nevada, and for over forty years was practically the only one employed in large stoping operations throughout the world. In some districts other and better methods have been evolved, though the square-set is still employed where no better way has been found to meet the existing conditions, and it is likely to be used in such places for years to come. Stoping with little or no timber, top-slicing, and various other methods have replaced the very useful Nevada square-set. Elsewhere herein will be found a rather startling proposal, by Mr. G. E. Wolcott, to dispense with blasting in underground mining, substituting channeling and the wedging out of blocks of solid rock, for the usual method of breaking the rock with dynamite, or other blasting agent. The proposal is startling, even revolutionary, and there seem to be many obstacles to its successful adoption, at least from an economic standpoint. Doubtless a machine could be designed to accomplish all that Mr. Wolcott proposes in the cutting of channels, but the breaking out of the solid blocks of rock between the channels is a matter that seems to interpose some difficulties, particularly as to the element of time required to accomplish it. By the intelligent employment of what are known to quarrymen as 'feathers and plugs', no doubt, the rock could be broken out by driving the plugs with a pneumatic hammer. How rapidly this could be accomplished on rock sections 20 inches or more in thickness, with only 4 feet or thereabout, between the ends of the channels, is wholly a question of trial. Moreover, some rocks would doubtless yield much more readily than others—a hard brittle rock, for instance, breaking possibly with comparatively little trouble, while a tough hornblende rock might resist to such an extent as to render all efforts futile. Mr. Wolcott says that the size of the blocks to be broken may readily be controlled, suggesting that if the channels be first cut only a foot deep, smaller blocks may be broken out than where the channels are cut deeper. This is true, if they could be broken at all, but to break a block of solid rock 20 inches thick with channels only 12 inches deep looks, upon the face of it, as though it would prove to be a difficult operation. Undoubtedly it would be easier to break the rock if the channels were cut 3 feet deep, as well as 4 feet or more wide. As a result, the blocks would be larger than are generally desired in mining operations and these would have to be broken before handling, which would cause the expense of mining to increase materially. The method of mining coal by what is known as 'undercutting' is, to a limited extent, not unlike the proposition suggested by Mr. Wolcott. All mining men, from shoveler to manager, are familiar with the effect of the gas due to the explosion of nitro-powder underground, and if any mining method can be introduced which will in some measure reduce this evil, the inventor will confer a great boon upon those who work in metal mines, and particularly in those that are poorly ventilated. It may be that by cutting a channel four feet deep across the face of a drift at the bottom and then putting in a round of ordinary drill-holes, the ground may be more easily broken, with fewer holes and much less powder than by the method usually employed in breaking a four-foot round. As to the cost of channeling, the figures submitted by Mr. Wolcott are extremely doubtful. He quotes a cost of 20 cents per square foot of area channeled. This may be a sufficiently liberal estimate, but is probably not, when the conditions under which the channeling must be done are contemplated. Channeling in a quarry in the open air is quite a different matter from working in the face of a drift underground, aside from difficulties due to the condition of the air and the necessity for timbering.

On the whole, the proposition of Mr. Wolcott is merely suggestive, and may stimulate experimentalists, those of investigative minds, to give the channeling machine a trial with a view to ascertaining what results may be possible. Should there be any such, we sincerely hope they will not withhold the result of their experiment but give it to the mining fraternity through the medium of our columns. To us, the plan seems mechanically possible, but economically, far from desirable.

Thunder Mountain Landslide

By Karl Baumgarten

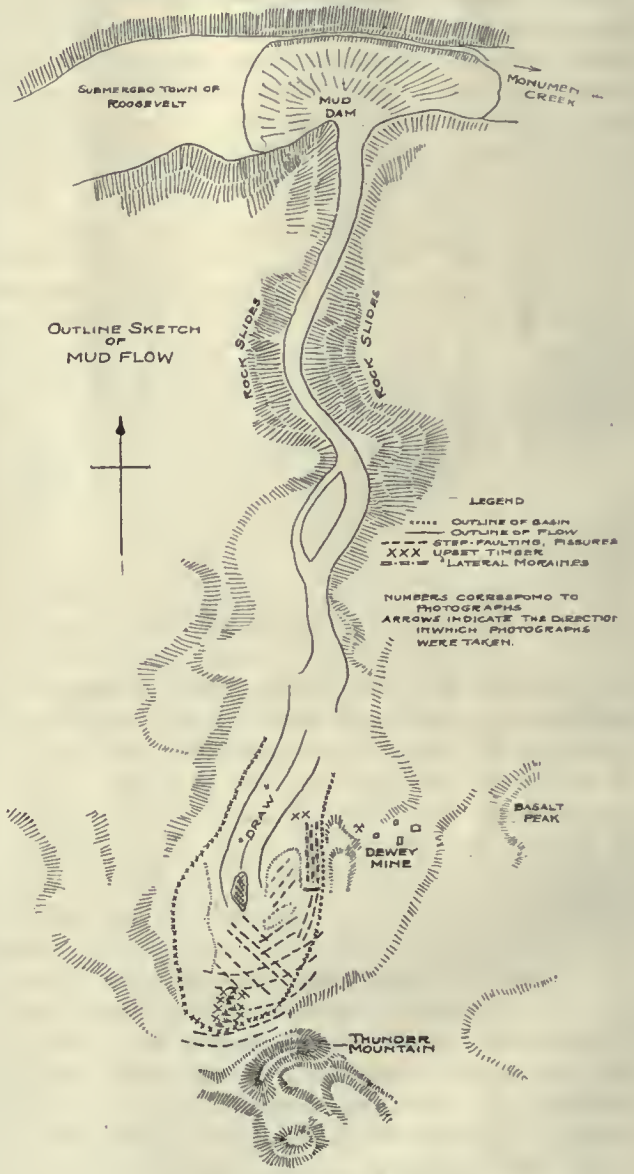
Somewhat more than a year ago there occurred a mud flow nearly three miles in length, damming back a stream to form a lake which flooded the town of Roosevelt in the Thunder Mountain mining district of central Idaho. The town lay at an elevation of 6000 ft. in a narrow valley between steep rock slides on Monumental creek, at a point immediately above the junction of Thunder Mountain creek with Monumental creek. In ascending the former, the steep rock slides are especially prominent at a point about a mile north of the Dewey mine, just before entering the zone of the decomposed lavas pertaining to the Thunder Mountain mining district proper. From the Dewey mine to the base of Thunder mountain there is an area or basin at an average elevation of 7500 ft., less steep than the topography south of Thunder mountain, which lies three miles south of

Town of Roosevelt, Looking Down Stream Toward the Mud Dam

the town of Roosevelt, or at Roosevelt itself. Thunder mountain rises to an elevation of about 8500 ft.; the name was applied to this mountain by pioneers who were disturbed by its rumblings in clear as well as in stormy weather, by day as well as by night. Geologically, the mass of Thunder mountain contains a succession of lava flows and intrusions of several types and ages, in various stages of alteration, but in the main highly decomposed. Though no previous mud flow has been recorded, the recent flow indicates what has probably gone on for ages past, and there is evidence on the south side of Thunder mountain that just such flows have taken place there on a smaller scale than this one which is recorded on the north side.

The history of the flow here described is as follows. Early one evening in May 1909 a man started from Roosevelt to return to the mines near the base of Thunder mountain; but after a short absence he returned, saying that he had encountered a 'river of mud' at a short distance above town, and that it was moving rapidly down. Several of the inhabitants sauntered down to the lower end of town where Thunder Mountain creek comes in. They looked and hurriedly returned to prepare to leave their homes. The mud flow with its débris of rock and timber reached Monumental creek during the evening and 'fanned out' both up and down stream, effectually damming the creek. Monumental creek was swollen by the melting snows at its headwaters and at 2 a. m. the town began to be flooded. At 8 a. m. the water had reached the second stories of the cabins, and within the day those same cabins were afloat upon a lake 30 ft. deep, 1500 long, and 300 across.

That area or basin which commences northwest of the Dewey mine and extends southward to the foot of Thunder mountain, is roughly a half mile wide and a mile long. The basin is covered in winter by great depths of snow which, upon melting, in the spring,



Landslide at Thunder Mountain.

saturates the underlying mass of decomposed rock. The latter is granular and only slightly cohesive, so that when thoroughly wet it lets go. Slipping and movement takes place each spring in greater or less degree up to the very foot of the mountain. The comparatively solid masses which form the Dewey mine, though now lying at a distance of a half mile from Thunder mountain, undoubtedly once formed a part of the mountain; that the mass was moving even before the time of the mud flow is evinced by the complaint of the mill workers that they could not keep the machinery in alignment. Where no other physical sign is outwardly visible the inclined

position of the trees, upset by the changes in level or even by the 'drag' of the moving mass, indicates that movement has taken place. Stepfaulting is concentric with, diagonally across, or even parallel to the smaller basin or 'draw' from which the bulk of the material for the mud flow came. The throws of these faults are found to be from the scarcely perceptible up to 30 ft. or more. Formerly a road wound through the basin, and this road has been rendered impassable to wagons by the sharp steps

The Mud Flow at the Slides.

of the faults. Along the edges of the main movement boulders are cast up in furrows parallel to the direction of the movement, exhibiting all the appearances of the lateral moraines of a glacier. Close to the foot of these a bridge has been moved to a point 100 ft. north of the original road. According to the accounts, the walls of the 'draw,' a quarter

Junction of the Creeks Where Monumental Creek Cut a New Channel.

mile in length, stood nearly vertical for a height of 90 ft. and 250 apart.

Of the more solid particles carried down by the mud flow, the boulders are becoming disintegrated where exposed at the surface as a result of air-slacking or frost action. In spite of the solid materials, the yielding character of the thoroughly wetted mass of the mud flow prevented any apparent scouring action along its path. The melting snows of the past spring have cut new channels through the mud flow, and at one point disclose a thickness of about 30 ft. The rate of flow was estimated to have been 6 ft. per minute. If this is true it is surprising that the people of Roosevelt were not sooner warned.

The Mining and Smelting Industry of Colorado

By Franklin Guiterman

*In its recent call for the Annual Convention of the Mining Congress, the invitation said in part: "Within the last three years, it is safe to say, the total annual output of mineral, coal, and oil wealth in the United States has decreased not less than 25% and perhaps 33%." Presumably this startling declaration was founded on statistics furnished by the United States Government, and may in consequence be accepted as true. In Colorado the falling off in mineral production has been confined practically to gold, silver, and lead, especially silver and lead, and the decrease has been so startling as to lead this Chamber to appoint a committee whose chief function is to make a thorough inquiry into the causes for the decadence of our mining and smelting industries, and to suggest means for their revival. I am advised that it is the custom of this Chamber to call for reports of progress from its several committees from time to time, and, as chairman of the committee on mines and mining, I have been requested to say something to you about the present status of the mining and smelting industries in Colorado, and to indicate in some measure the results which have followed our investigations to date. If your committee is not able at the present time to furnish the Chamber a specific report on the important matters which have engaged its attention, it may be said in extenuation that your board of directors was advised initially that the work which has been undertaken is one of magnitude and that the gathering of the necessary data would involve much time, detailed labor, and analysis. It is not unlikely even that failure to secure the desired and necessary information may result. At the present time it is too early to state what the outcome of our investigations will be. It may, however, be permissible to dwell briefly on some of the more important causes which have contributed to the decadence of mining in Colorado with the coincident enforced curtailment of the smelting industry, which is dependent thereon. It is most unfortunate for our State that the impairment of the mining and smelting industries has from time to time been made a political issue, and that in discussing these vital industries, some have not hesitated to misrepresent the facts, and thus mislead not only our own citizens, but also those from other States. It is unfortunate that the subject of ore-treatment charges and of ore schedules is complex: that the metallurgical processes are intricate and technical, and that the metal recoveries attendant on these processes are sometimes astoundingly variable and often uncertain in their outcome. Coincident with these technical considerations comes the application by smelting and milling companies of tariffs, or ore schedules, as they are termed, and

*Abstract of an address read before the Denver Chamber of Commerce.

as these schedules vary greatly with the character as well as the value of ore, it appears, superficially considered, that the rates of payment for metals in ores are not only complex and sometimes incongruous, but that they are framed with the specific underlying idea to confuse, if not to deceive, the ore seller. To him, however, who is familiar with the marketing of ores, a familiarity which comes with mining and commercial experience, there is nothing obscure or involved in the schedules; and for him it is a simple matter to resolve at once the terms of payment for his ore into a net value per ton. The more complex the ore, considered in its mineralogical character, the more complex apparently is the ore schedule on which the mill or smelter buys it. To illustrate:

The simplest tariffs are those applying to ores which are treated in a stamp-mill, where the ore is stamped, passed over amalgamated plates where the gold is extracted to as large an extent as possible, and the tailing treated on concentrating tables. In this case the millman charges the ore producer a fixed sum per ton for milling the ore, and turns over to him the gold amalgam and the concentrate. The amalgam is retorted and the gold sold to the Mint, while the concentrate is sold to the smelter on a simple schedule, because the product is simple in its mineralogical nature. The second case is that covering such ores as the Cripple Creek gold ores, in which a fixed sum per ounce is paid for the gold content and an increasing treatment charge per ton is applied as the ores increase in value. The last case is that involving the purchase of ores, complex in their mineralogical character, which may contain gold, silver, copper, lead, zinc, bismuth, antimony, and arsenic. Such ores in smelting involve the production of by-products which demand repeated metallurgical treatment. In these processes the recoveries of the metals, gold, silver, lead, and copper, are dependent on technical skill. The payment for recoverable metal content in such ores is governed by the ability of the smelter to effect certain savings which experience has shown can be attained, and the treatment charges of the ore schedule must be based not alone on the expense obtaining in the actual smelting operations, but on the technical considerations governing possible metal recoveries as well. Ores known as fluxing ores, and without which the latter could not be smelted, have the lowest treatment charges applied to them regardless of the smelting expense, while other ores which demand fluxing ores in smelting have to bear greater smelting charges. This is a natural as well as a commercial distinction, for the fluxing ores are, almost without exception, low grade, while the siliceous ores are generally of higher value. Therefore, smelting schedules must apparently become more complex with increasing complexity of the ore to be treated. It is impossible to frame the schedules in a manner which will readily be understood by those inexperienced in ore production and ore rates, and those unfamiliar with the mining and smelting industries.

Notwithstanding the continued efforts on the part of milling and smelting companies to extend aid to the mining industry in Colorado, the result has been a continued recession from the high level of prosperity which it occupied a decade ago. The extraordinary decline in production for this period will be seen from the following comparison:

	1900.	1909.	Decline, %.
Gold	1,400,000 oz.	1,061,000 oz.	24.21
Silver	20,300,000 oz.	8,900,000 oz.	56.16
Lead	82,137,000 lb.	32,360,000 lb.	60.60
Copper.....	No change.		
Zinc	Increasing in output.		
Total decrease in value....	$50,314,000	to $30,916,000	38.55

Colorado's ability to maintain its gold production even on the present level has been due alone to continued reductions in treatment charges, those on Cripple Creek ores having been reduced in the last ten years about $5 per ton on the average. The efforts of the smelting companies to check the decline in production of the silver-lead ores have been entirely unavailing, notwithstanding reductions in treatment charges aggregating on this class about $3 per ton. Not only have the heavy reductions in treatment charges not resulted in the maintenance of the former tonnage production, but with the steady decline in the mineral output, the American Smelting & Refining Co. has been obliged to put one-half of its Colorado plants out of operation and operates the remainder on curtailed capacity.

It is true that prospecting in Colorado has practically ceased for many years; that the orebodies which heretofore furnished ore for the smelters have been exhausted to a large extent, or are approaching that stage; that to a large degree mining properties once operated under company management are now worked by lessees, and that in most cases development work is being neglected; and finally, that in closed mines where orebodies have been exhausted, or only ore of too low a grade is left, or where such physical disadvantages as the necessity for an ore concentration plant or a heavy pumping equipment has to be faced, the investment of new capital is demanded. Such capital, however, will not be forthcoming unless it is made clear to the investing public that Colorado still offers a profitable field for mining ventures when undertaken and guided by competent and conservative management. The desired end can only be accomplished by cooperation all along the line, between mining, milling, and smelting interests, railways, and by the press in inviting mining investors to come to Colorado with the assurance of square and fair dealing on the part of ore-purchasing concerns.

Colorado's metallurgical engineers, that is, those who have acquired their initial experience in this State, have indisputably stamped their individual equations on metallurgical progress the world over. It was their efforts which have wrought success in the mineral fields of South Africa, New South Wales, and Australia. It is to them that the astounding and astonishingly successful copper milling and smelting methods in Montana and Utah are due. It is they who have placed the chlorination and cyanide practice of the Cripple Creek field on a higher

plane of metallurgical achievement. It is they who have created a practice of silver-lead smelting which is acknowledged as one to be patterned after in other States, and it is they who are now utilizing to the best and largest extent our present mineral resources and who may be trusted satisfactorily to take care of those which our pluck and energy may yet bring to light.

If indications point aright, there is reason to believe that our mining conditions will greatly improve in the near future. With the deep-drainage tunnel practically completed at Cripple Creek, new and increasing tonnages may be looked for from that section; with the discovery of important bodies of zinc carbonate at Leadville a new impetus will be given to enlarged development and operations in that district, which in truth furnishes the basis of our smelting industry; and with the renewed activities in those two districts and an advancing price of silver, we may confidently expect an awakening and quickening in all of our other mining camps.

THE OUTLOOK FOR ZINC

The zinc situation is attracting a great deal of attention. Consumption of spelter has more than doubled within the past ten years. When the expansion first began to make itself felt, a large number of zinc smelters were erected in Kansas, where they were near the lead and zinc mines of Joplin and Baxter Springs, and where a cheap supply of natural gas could be had. The exhaustion of the natural-gas fields is apparently near at hand and the retorts in the Kansas field will soon be forced to close. Of 94,000 retorts in the country, 50,000 are in Kansas, and of these, 30,000 are in or near the Iola field, where the gas supply is already so far diminished as to put half of the smelters out of operation. The balance are soon to face the same conditions. Coal smelters, operating 5000 retorts, have for one reason and another been shut down, with the result that the total capacity now available is not more than 70,000 retorts under the most favorable conditions, which means a production of 200,000 to 225,000 tons, as against a normal output of 275,000 tons. The only solution of the problem is a probable reversion to coal smelters and the erection of new plants. To do this will require the greater part of two years. In the meantime, higher prices for spelter are predicted. East St. Louis, which is the spelter market, is quoting 5¾ to 5⅞c., and 6c. is predicted in the near future.

Placer claims located to secure tailing deposited thereon, or passing down the canyon, can only be taken on unappropriated land. If the tailing is on a quartz location no other than the owner can go upon the claim and appropriate the tailing, as a stranger would be a trespasser with no right to place stakes on such quartz claims. It may be that some method can be applied which would cause the tailing to be carried down stream to land where it would be available. The better way would be to secure a lease from the company owning the tailing pile, and work it under royalty.

Gravel Elevation in Siskiyou County, California

By Charles S. Haley

Although it is generally known to the mining fraternity that a large portion of northern California is unaffected by the débris law with regard to hydraulic mining, nevertheless that portion, which may be briefly described as that country which is tributary to and drained by, the Klamath river, has not been very extensively advertised or examined in the last two decades. This region, comprising a large part of Trinity county, the northern half of Humboldt county, the eastern portion of Del Norte, and almost the whole of Siskiyou, has for many years been a steady and prolific source of placer gold. It is of some of the more recently applied methods of handling the deep-channel gravels that it is the purpose of this article to treat; more especially of methods in use in Siskiyou county. In the early history of the State, the camps of Rough and Ready, Scott's Bar, and Happy Camp, on the Scott and Klamath rivers, as well as Sawyer's Bar, Forks of Salmon, and Some's Bar, on the Salmon river, poured forth their golden stream through the agency of every nationality in the world. Chinamen by the thousands, negroes, Portuguese, Indians, Frenchmen, and Yankees, all lived more or less peaceably side by side. It is estimated that 35 years ago there were 3000 people mining between Forks of Salmon and Some's Bar, a distance of 20 miles. The South Fork and the North Fork of the Salmon had also their separate quotas, and though the country was destitute of wagon roads, and all machinery and supplies were packed in on muleback (as they still are today to a large extent), nevertheless, the country was prosperous. But the day of the wing-dams and of the ground-sluice is over. Conditions at present are very different. The easily worked gravel, with light top and accessible to water, has gone. The day of the giant, however, is still in its prime, and the difficulties incident to working on a large scale are ever present in this as in all other branches of mining. Perhaps the most difficult phase of the work in these districts, as in others, is the handling of the low bars, many of them ancient channels below the bed of the present river. A bar of this sort must, of course, be rich in order to pay for the expense of handling, even when operated on a large scale. In order for the tailing to be removed as fast as it comes through the boxes, it is necessary that the gravel be elevated. In the early days this was accomplished by the employment of gangs of men with pick and shovel, who threw the gravel up from one staging to another. This slow and laborious method is too cumbrous and costly for the modern mining corporation, therefore mechanical ways have been devised.

First, and simplest of all, is the plain giant elevator. If the channel, or depression in the channel, slopes up gradually to the head of the boxes, and the hole is not too deep to drive conveniently, one giant may be continuously employed in driving,

while another giant is running off the surplus water through a wooden trough or string of pipe leading from the bottom of the hole over the rim to the river. If pipe is used, the pumping giant is usually fitted with a gooseneck, leading up into the drain pipe. The suction draws the water off as fast as it comes back from the driving giant, permitting the latter full play to drive the gravel to the head of the boxes. A strong flow of lead water is, of course, kept running through the boxes all the time. This method of elevation is the simplest known, and is only practicable where the bedrock slopes off gradually and not to a great depth.

In cases where the depth is greater, and the slope abrupt, a pipe elevator for the gravel is sometimes used. This is more particularly used where the gravel is of medium size. A hole is worked out to greater depth than the rest of the channel, and all gravel of smaller size is driven into it, the larger

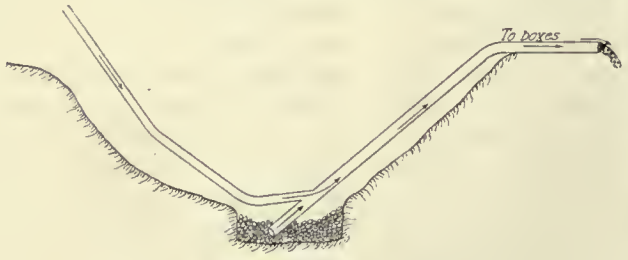


Fig. 1.

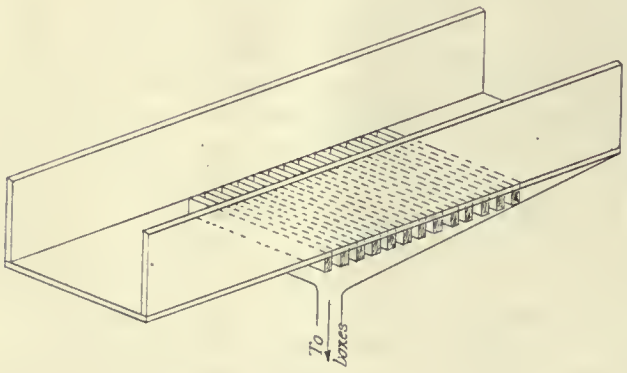

Fig. 2.

boulders being taken out with a derrick. Into this hole, and reaching to the bottom, runs the feed pipe. At the bottom end is a grizzly, to prevent congestion by the larger rocks. As shown in Fig. 1, the upper end of the elevator pipe dumps directly into the boxes. About six or eight feet from the lower end of this pipe is an intake-pipe, a couple of inches smaller, with a nozzle, so arranged as not to impede the flow of the gravel. The auxiliary pipe supplies the pressure for the pumping, and the suction at the bottom of the hole draws all the gravel that will go through the grizzly into the feed pipe. When the hole is filled with the larger gravel, it is cleaned by hand.

The third method with which I have to deal is perhaps the most effective of all, when used under proper circumstances, in connection with a derrick. It consists of an inclined chute, at an angle of 20 degrees, lined with steel. In most cases the width is about 12 ft., with a length of about 40 ft. The entire trough is lined with heavy steel plates, to prevent wear. The floor joists are 8 by 3 in., and after the first 15 ft. the solid steel plate changes to a steel-covered grizzly, the joists being set about 3 in. apart, the upper surface of each joist being covered with a 3-in. piece of steel, and a second steel-lined solid bottom being placed underneath, with a slope toward the boxes, which are placed directly underneath the point where the grizzly begins.

A head of lead water is kept running through the boxes. A pump of the kind first described, with an auxiliary giant, may be used to drain off the back water from the driving giants. One giant is used for cutting down and driving to the front of the elevator. The derrick handles the larger boulders. A giant is stationed in front of the elevator, and it drives the whole of the gravel up the incline. By the time it has passed over the 25 ft. of grizzly, all but the coarse rock has dropped through the grizzly and gone through the boxes.

The disadvantage of this method is that the elevator, though mounted on a track, with skids for rollers, is so cumbersome as to make the necessary removals in the natural course of working extremely difficult. This mode of elevation is, notwithstanding, perhaps the most widely used in that part of the country.

HORSE-POWER PER TON OF ORE TREATED PER DAY*

Type of mill.	Mesh.	Hp.
Stamps and vanners	20—40	0.75—1.0
Coarse concentration	10—20	0.5 —0.8
Combination stamp	16—30	1.5 —1.75
Chloridizing stamp (dry)	to 16	2.0 —2.5
Chloridizing stamp (wet)	to 40	4.0 —4.5
Magnetic separator		0.25—0.5
Cyanidation (dry) roll-crushing	20—30	0.5 —0.8
Cyanidation (wet), stamp crushing and sliming	to 80	0.75—1.5

*J. A. Barr, 'Testing for Metallurgical Processes.'

Where a prospector has discovered valuable mineral on railroad land, if the railroad company has not been granted a patent to said land, the discoverer of the mineral may legally locate mineral claims thereon, but must prove, if suit be instituted, that the land is more valuable for mineral than for agricultural purposes. If the railroad company has patent to the land the best way to do is to drop the whole matter, as it is a most difficult and expensive thing to set aside a Government patent to land. On February 26, 1897, Congress provided for commissioners to determine the character of railroad lands in Idaho and Montana, this referring to the odd-numbered sections. This commission has hearings, and reports its determinations to the land department. Its classifications, however, are only final when passed upon and approved by the Secretary of the Interior. Where land is classified as mineral by the Department of the Interior the railroad title to such land is cancelled. Work done on a placer situated on an unpatented quartz claim cannot be counted as annual labor on the quartz claim.

Sheet rubber, hose, packing, and other rubber material will cut much more readily if the knife be wet first.

Origin of the Placer Gold of Guiana

By Lee Fraser

*There is a general consensus of opinion among those who have studied the geology of the Guianas as to the origin of the placer gold and the manner in which it has been concentrated in the so-called alluvial deposits of those countries. They consider that the gold has been derived from masses of acidic rocks: or concentrated from that disseminated through the mass of metamorphosed basic rocks, now altered to amphibolites, epi-diorites, and hornblende-schists, or in part contained in veins, or threads of quartz, which in places are abundant in them: or from the minute amounts of the metal disseminated through unaltered gabbro and diabase. De Launey[1] has stated that in French Guiana gold is often associated with diorites, which in places have decomposed, forming auriferous earth; and in the contested territory between French Guiana and Brazil, M. Bernard found gold in veins of quartz in diorite traversed by veins of granulite, the diorite being intrusive in the gneiss and hornblende-schist. E. R. Lunquitz[2] produced proofs of great importance in connection with the hypothesis of the derivation of the gold of the placers from the country-rock (aplite) at Omai, B. G. Further he has written that there is no gold district in Guiana without diabase, and the richest portions of the Guiana gravels are characterized by the fact that the fissures in that neighborhood, originally filled with diabase, have been again disrupted and occupied by aplite or diabase intrusions. The result was a thorough shattering of the hanging and foot-walls of these dikes, the filling of the adjacent fissures by quartz, and the enrichment of the fahlbands by gold ores. M. Levat[3] has pointed out that the placer gold of French Guiana has been derived from the decomposition of diorites and other greenstones. As far back as 1873 these rocks had been demonstrated to contain minute quantities of gold.[4] T. B. Harrison,[5] in considering the geology of the northwestern district of British Guiana, claimed that the placer gold and much of the precious metal in the auriferous quartz veins in that district are derived from the minute particles of gold disseminated throughout the basic rocks. He also says that the source of the gold in the Essequibo, Potaro, Konawarook, and Demerara river goldfields, is generally due to the intrusion of diabase. But it has also been derived from hornblende-schist and epi-diorite. Later, in the Cuyuni and Mazaruni districts, further proofs were adduced as to the derivation of placer gold by concentration of the minute amounts present in the rocks during their degradation to saprolite and to concretionary ironstone, or to more or less ferruginous gravely clays. Exception has been taken to the statement that the gold occurs in the unaltered diabase and gabbro,[6] it being argued, in accordance with the views of Lunquitz, that "the gold depositions follow the weakened and ruptured zones of certain pressure-planes in the basic dikes, in their contact with the older acidic rocks, or commonly through both." In French Guiana, Levat has emphasized the close proximity of the placers to intruded granite masses. Harrison has stated that the granitic areas themselves are characterized by the absence of placer deposits upon them. In British Guiana, Harrison has not found sufficient proof to enable him to accept the view of the inter-relation or dependence of the auriferous districts upon the intrusive granite. Levat, after examining amphibolite and hornblende-schist for the presence of gold, states that from two samples not showing free gold he obtained 1 dwt. and 1½ dwt. per ton respectively, while from a sample showing free gold he obtained 15 dwt. per ton. G. C. Du Bois,[7] in considering the goldfields of Dutch Guiana, has pointed out that gold is noticeably present in the saprolite originating from amphibolite, and from augite-plagioclase rocks, being a concentration of gold from the original rock; also, samples taken from various diabases have given him from 3 to 9 grains of gold per ton. Harrison has found gold in the diabase varying from traces to 17 gr. per ton, while samples taken from diabase in contact with acidic rocks, yielded gold at 26 gr. per ton. Lunquitz has found gold in various rocks, among which are diabase and gabbro. Samples of epi-diorite, amphibolite, and hornblende-schists have all yielded gold at rates between 3 gr. and 2 dwt. per ton. At variance with this, Phillips and Louis[8] state that in British Guiana "quartz veins occur mostly in metamorphic schists and gneiss and nearly all the streams and rivers that traverse regions occupied by the above rocks, or by granite, are gold-bearing." J. E. Spurr[9] arrives at the conclusion that in British Guiana the deposition of the gold ores represents one of the closing phases of the great granitic intrusions, and that the basic dike rocks with which the gold ores are associated, as well as the silicious dike rocks in connection with which they are also frequently found, are representations of the general process of granitic injection, earlier than the veins, but subsequent to the main intrusion. Harrison states that his observations tend to prove that the occurrence of placer deposits, veins having gold-bearing quartz, and masses of mineralized rocks, are characteristically accompanied by the effects of dynamo-metamorphic forces, and are governed by dikes of basic rocks, either the gabbros, epi-diorites, or hornblende-schists, or the unaltered diabase.

Under the conditions prevalent in the Guianas, and in other parts of the tropics where constant high temperatures associated with very heavy and frequent rainfalls cause a rampant growth of vegetation, igneous rocks of all types are subject to relatively rapid decomposition. The insoluble products of this decomposition, wherever shielded from erosion by forest growth, remain in place as a protective cover to the deeper-seated rocks. Under favorable conditions, this covering material attains a depth of 200 ft. Basic rocks of the diabase-gabbro type are readily subject to chemical decomposition under tropical conditions. The action being almost purely chemical, affects the sheared members of the group, such as the epi-diorites and hornblende-schists, in which the numerous planes of foliation allow ready access to the interior of the mass, more than it does with the massive members (unaltered gabbro and diabase), which yield only on their bounding surfaces and along their relatively few joint planes. The resultant products of this decomposition consist in buff-colored, red, brown, and chocolate-colored ferruginous, usually siliceous earths and clays or laterites. Numerous instances are cited as to the extent of the solubility of gold, contained in the country rock by the soil-waters. Lunquitz has shown that the ashes of the trunks of trees that had grown on the gold-bearing saprolite in the district of Omai, B. G., contained small quantities of gold, varying from 2 to 10 gr. per ton of ash from wood at the base of the trunk, to 28 gr. per ton from ash near the first branches. Harrison subsequently performed a similar experiment for the purpose of verifying the data obtained by Lunquitz and secured corroborative results. He found that the ash from the bark of the tree contained 1 gr. of gold per ton of ash, while from the interior of the trunk he obtained from 7 to 10 gr. The water of Omai creek was also found to contain gold in solution. Various observed phenomena may be interpreted as accounting for the concentration of gold, in placers, veins, and mineralized masses, upon a basis of both mechanical and chemical action. The decomposed rock, saprolite in many places, because of the minuteness of the particles composing it, is highly absorbent of water, and when saturated, has the consistence of a viscous liquid, transmits hydrostatic pressure, flows more or less freely under the influence of gravitation, and permits the settling through it of grains and particles of the heavier minerals which it contains. The gold-bearing saprolites situated high upon the hillsides afford striking examples of this action of mechanical concentration of the quartz gravels and heavier minerals, which sink to form a well defined layer at a point where the saprolite loses its viscosity. Lunquitz has stated,[10] as the result of years of experience in British Guiana, that "a great portion of the placer gold owes its existence to chemical concentration." In connection with the concentration of the gold the theory as proposed by Spurr, is well worthy of note. The older gabbro, wherever found unaltered, contains areas, and especially interstitial spaces or patches, of a micro-pegmatite composed of feldspar and quartz, and by far the greater number of specimens of diabase which have been examined show a similar structure, while in places the diabase passes into a quartz-diabase, or into an augite-granophyre, some samples of which are gold bearing. It is quite possible that the occurrence of gold in the basic rocks of the colony is more or less closely connected with the presence of the quartz-feldspar micro-pegmatite, and that the micro-pegmatite areas in the basic rocks may be examples, on a minute scale, of 'magmatic quartz veins' and may have served as the feeders of gold from the magma to the iron ores of the basic rocks. Varying quantities of oxides of iron set free during the decomposition of the basic rocks are reduced to or are already in the state of ferrous iron, and, becoming dissolved in percolating waters, move through the mass of the laterite. A part of it may exist in solution as ferrous bicarbonate, and this, when brought under conditions where that compound becomes disassociated, is thrown out of solution and oxidized, forming coatings and layers of limonite. Other parts are held in solution by the organic acids of the surface waters and may be leached out of the laterite, but as the solution undergoes oxidation with the attendant destruction of the acids, the oxides of iron are deposited as limonite. The limonite either forms pisolitic grains or, more commonly, surrounds grains of sand, binding them together where abundant, into ferruginous sandstone, or where they are less abundant, using them as nuclei for the formation of masses of impure concretionary ironstone. Some of these masses are of great size and form blocks largely exceeding a ton in weight.

It is a common occurrence in auriferous districts of Guiana, that large areas of the sides and tops of hills composed of basic rocks are covered with gossan. The surface layers and the great blocks of concretionary ironstone generally form ruddy colored cindery-looking masses with numerous small cavities. As a final step in the local degradation of the rock, the products of its decomposition are washed from the side slopes to be re-arranged in the ravines and valleys as beds or deposits of gravel, ironstone, or ferruginous conglomerate. During the decomposition of the country rock the gold therein contained is dissolved in the soil-waters to be later re-deposited in fissures or cracks, or upon already existing particles of gold, or concentrated in the ironstone. In this resumé an attempt was made to elucidate the phenomena of the origin of the gold in the veins and placers of tropical countries, and in summing up the facts, hypotheses and theories herein presented, it is concluded that gold occurs disseminated throughout the country rocks: that under the action of the surface waters these rocks suffer rapid decomposition due to the chemical qualities of the waters; that among these products of chemical decomposition is gold dissolved in the surface waters; and that this gold, in solution, is chemically and mechanically concentrated to form gold-bearing deposits.

Porcupine, the New Gold Region of the Far North

Canada has within recent years supplied her share of mining excitement. Rossland, in British Columbia, has been a famous copper-gold camp; Cobalt, Ontario, has developed wonderful mines of silver; and now Porcupine, in the far north country, well up toward Hudson's Bay, is attracting world-wide attention to what appears to be phenomenal gold-bearing veins. *The Canadian Mining Journal*, with commendable enterprise, has fully described the trail into Porcupine, and the geology of the new goldfield, in its issues of October 15 and November 1. Both articles, written by R. E. Hore, are profusely and handsomely illustrated, and contain much of interest and value to those seeking knowledge of this newest Canadian gold region. Following is a description of the Porcupine goldfield, from the issue of that journal of November 1:

The gold at Porcupine occurs chiefly in pyritic quartz. In lesser amounts it is found in the country rocks. The quartz in most cases is white in color, with reddish-brown patches of iron oxides. Less commonly, but including some spectacular veins, the color is grayish blue. The gold is, in part, coarse and readily visible to the eye. In most of the quartz, however, it is very fine. The greater part, 50 to 65%, is readily won on crushing. A smaller percentage is more intimately allied with sulphides and will probably be treated by cyanidation. The country rock is usually either pyritic gray schist or rusty weathering mixed carbonates. Less often it is a conglomerate. The schistose country rocks are for the most part altered volcanics, and are of various types. Many are sericitic and all are impregnated with carbonates. Small cubes of pyrite are usually abundant. Copper pyrite occurs; but in subordinate quantity. The carbonate rocks are gray to yellowish gray, crystalline, and massive. They are iron-calcium-magnesium carbonates, such as are common in the iron formations of Ontario and the Lake Superior States. Such rocks range in composition from siderite through ankerite to dolomite, and on the iron ranges are called ferro-dolomite. The percentage of iron in the Porcupine rocks, as in most Keewatin carbonates, is less than in normal ankerite. The conglomerate is composed of light colored pebbles of various types set in a fine gray colored matrix. An arrangement of the pebbles with their longer dimensions parallel, gives a decided schistose appearance. The deposits vary greatly in shape. Some appear at the surface to be well defined single fissure fillings or veins. In some cases there is a series of fissure fillings running nearly parallel and enclosing large and small masses of rock. These are conveniently referred to as vein systems. In another type numerous quartz veins run through ferro-dolomite beds. There are also large quartz masses of irregular and unknown form, which cannot be well designated as veins or lodes. They appear to be lenticular rather than tabular in shape. From the nature of outcropping surfaces, they have been called 'domes.' Until their true character is known, it seems best to refer to them as quartz masses. These four types may be illustrated by description of four claims in Tisdale township. For a single quartz vein, take one on the Connell property. A system of quartz veins is exposed at the Timmins mine. The most striking example of quartz-ferro-dolomite lode is the Foster. A remarkably large quartz mass or 'dome' is that at the Dome mine. None of these deposits has been thoroughly explored, and observations on their nature must therefore be confined almost entirely to superficial characteristics. The Dome is being tested by drifts and cross-cuts at the 60-ft. level, and by diamond-drilling to a few hundred feet. One of the veins at the Timmins is being driven on at the 100-ft. level. The Foster lode and the Connell vein have each been carefully stripped; but neither has yet been tested for more than a few feet in depth. The deposit selected as an example of this type is on the Connell claims, just south of the centre of Tisdale township. The vein has been exposed almost continuously for over 200 ft. At the western exposure it is 15 in. and at the eastern, where it dips into low ground, 5 ft. wide.

The quartz is milky-white and vitreous. Where it has been directly exposed to the weather, it is coated with yellowish brown iron oxides. Streaks and patches of this secondary material are found filling small cavities and crevices for a few feet downward. Portions of the vein which were protected by a mantle of soil, show similar alteration, but to a much less degree. Some such portions show scarcely any weathering and appear brilliantly white in the sunlight. Free gold can be seen for several feet along the vein. It is coarse and readily detected by the naked eye. The most spectacular and richest portion is a streak about 15 in. wide on the north side of the vein. Here countless particles of coarse gold appear on the surface. It occurs especially in rusty cavities and in minute dark streaks, which fill crevices in the quartz. The gold particles are even more numerous, however, on the vein-wall. This wall is clean cut, and has a thin selvage of dark greenish color. It is slickensided and shows pronounced grooves running nearly vertical. These grooves, running normal to the undulatory strike, produce a decidedly corrugated surface. The wall rock is a rusty-weathering ferro-dolomite. At the immediate contact it is disintegrated for a foot in depth. A foot or more from the contact it is quite massive, except for a few inches at the surface. The fresh rock is of light gray color, finely crystalline and soft. It effervesces slowly with dilute acid. Scattered through it are striated cubes of pyrite. Veinlets of white quartz penetrate in all directions. The carbonate on the north wall is only a few feet wide, and is succeeded by dark-colored, fine-grained porphyritic igneous rocks. South of the vein the rocks are not exposed. At the Timmins mine there are a number of large quartz veins striking in a northeasterly direction. Some of them are but a short distance apart and appear to converge and enclose large masses of rock. Others running parallel, and supposedly of the same vein system, are 200 and 400 ft. apart. The larger

members of the system themselves enclose numerous fragments of schist similar to the country rock. This vein system appears to be part of a larger veined zone, which extends northeast to and north of Pearl lake. The quartz is in most of the veins white in color, except where stained brown with iron oxides. An exception is a vein of grayish blue color, which cuts across one of white quartz. The veins are commonly 4 to 10 ft. wide, and one vein, now being developed from two shafts 250 paces apart, is 8 to 15 ft. wide. There are a large number of veins which show free gold on the surface, generally in rusty patches or in minute fractures. The ore from a few feet below the surface is remarkably free from iron stains, and the pyrite crystals have scarcely any tarnish. Ore impregnated with particles of coarse gold has been taken from a drift at the 100-ft. level, and it is more spectacular than any of the surface showings. The workings are in ore at almost all points, and the ore is high grade. The wall rock is a gray pyritic sericite-schist impregnated with carbonates. The pyrite occurs both as small cubes scattered through the rock, and in less perfect crystals in little veinlets. C. W. Knight has suggested that the schist is an altered phase of quartz porphyry, which occurs in the vicinity. It is similar to, but not so silicious as, some of the sericite schists at Temagami, which Dr. Barlow showed to be mashed quartz-porphyry. It is as yet impossible to trace out the individual members of the vein system. Many of the outcrops are small and separated by low ground. The strike of veins on neighboring outcrops is frequently too divergent to permit the interpolation. Considerable stripping has been done and a few veins traced continuously for several hundred feet. A remarkable outcrop is the grayish-white quartz 'dome' beside which No. 1 shaft has been sunk. For the greater part it shows a marked similiarity to some marbles. In places it is stained with iron oxides, and in such rusty patches are many particles of coarse gold. The exact relation of this mass to the vein in the shaft is not evident. From the far side of the shaft-house, a vein 3 ft. wide, runs northeast for a few paces and then is lost in low ground. Several hundred feet along the strike another outcrop shows similar quartz. Southwest from No. 1 shaft there are fairly continuous outcrops of quartz, which are probably parts of one vein, and which have been tested by two shafts. From the farther shaft a drift is being made at the 100-ft. level toward No. 1. In some outcrops east of No. 1 shaft a variety of structure is shown by quartz veins in the schists. In some places the veins cut distinctly across the foliation of the country rock. In others there are veins of similar quartz which conform closely to the schistosity and terminate abruptly in the sharp folds. On the Foster claims, gold occurs in quartz veins which run through a band of rusty-weathering ferro-dolomite. The largest lode has been stripped for about 250 paces. It shows a width of 5 to 20 ft., and for a considerable portion of its length averages over 10 ft. The quartz stands out in relief from the more deeply weathered, red brown, oxidized ferro-dolomite. Several quartz bands, 4 to 10 in. wide, run normal to the strike of the lode, and the carbonate is impregnated with a multitude of small quartz veins. Many of the latter occur in two sets which divide the carbonate into small rectangular blocks. The quartz is white in color, but stained with iron oxides. The red rust comes partly from the oxidation of small pyrite crystals, which are abundant in patches of the quartz, and in part from the weathering of the ferro-dolomite. In some of the rusty crevices there are spectacular showings of coarse gold. The lode strikes nearly due west. The country rock is a pyritic gray schist impregnated with carbonates. At the Dome mine a smooth outcrop glistens white in the sunlight. It is chiefly made up of huge masses of quartz which enclose large and small fragments of gray schist. The country rocks are gray sericite schist, gray slate, and a schistose conglomerate. One mass, which is almost entirely quartz, has a surface area 100 by 200 ft., and there are numerous smaller masses of elliptical plan. An oval-shaped area, including much country rock, but of which about one-half is quartz, is 200 by 600 ft. In addition to the large masses, there are numerous veins one to three feet in width, which penetrate the country rock. Some of these are almost conformable with the schistosity, but many cut distinctly across it. The dome-shaped masses show rather varied relations to the enclosing rock. In some cases the contact is nearly vertical, while in others it is but gently inclined. The boundaries are seldom nearly straight lines, but elliptical or circular. Coarse gold shows at several places on the surface. It, together with pyrite, is especially abundant in the vicinity of enclosed schist or the country rock. A large tonnage of quartz carries workable quantities of fine gold. The pyritic schist itself is known to carry some gold. Small striated cubes of pyrite are abundant in both the schist and the quartz. Copper pyrite also occurs, but it is probably not in such quantity as to interfere seriously with the recovery process.

Photographs of head-frames, machinery, or frame work of any kind, where the photos are intended for reproduction in books or papers, should be taken on a dull day, or at a time when the sun is not shining directly on the object to be photographed. The bright sunlight will cast many confusing deep shadows, which lessen materially the value of the picture. Do not over print an exposure, as the detail is lost and the illustration fails of its purpose. Always aim to get a good exposure of the principal object, regardless of artistic effect. If a mill is to be illustrated, and a Mexican chances to come into view with a squeaking native cart, never mind the cart and driver—get the mill, then turn your attention to the Mexican outfit and get a good exposure of that subject. A great many pictures sent in for re-production—the majority, in fact—are practically useless, due to the various causes above referred to.

Zincblende may be readily detected by applying a drop of hydrochloric acid, which will at once cause the evolution of sulphuretted hydrogen, recognized by its odor, that of rotten eggs.

A Revolution in Mining Methods

By G. E. Wolcott

No excuse is needed for presenting the following discussion, nor for proposing a rather radical departure from present accepted practices and ideas. The excuse already exists in conditions which prevail in nearly all metal mines throughout the United States and throughout the world. In our day we are inclined to pride ourselves upon the advance which has been made both in mining and metallurgy during the past century, and there is indeed large grounds for congratulation. The invention of high explosives and their adaptation to the use of the miner in breaking rock, the development of the rock-drill, and later of the air-hammer machine and other improvements have contributed toward lowering the cost and extending the field of mining operations. Undoubtedly the greatest factor in the advance made has been due to the use of high explosives, and in our day it is hard to conceive of mining operations carried on without their use.

We are told that in olden times rock excavations were made by building fires against the face of the rock and, after heating, cooling the surface suddenly by the application of cold water. We would be apt to smile at the application of such a method today, and yet, in certain respects, the method now generally in use presents no very great advance over ancient practice. The physical conditions induced by the explosion of 50 lb. more or less of dynamite in the face of a drift are certainly no more conducive to a healthy condition of the atmosphere than are those produced by maintaining a fire against the breast. In either event the air is heated and contaminated by gases to such an extent as to be unfit for the maintenance of human or of any animal life. Where ventilation is good it is true that conditions quickly improve, but unfortunately in most metal mines ventilation is seldom good, or even approximately fair, except in certain portions of the mine. This is particularly true of the lower levels before connections can be made, and daily men are compelled to work under atmospheric conditions which are a disgrace to our boasted progress in mining methods. The casual visitor underground may not realize these conditions, but the man who does the work and who is compelled by force of necessity to grope his way through powder smoke so thick that he can scarcely discern the glimmer of his candle, and who is compelled, with smarting eyes and throbbing head, to proceed to the face of the drift or raise and there make ready to repeat the torture for the benefit of the succeeding shift, realizes them to their fullest extent.

I am aware that any proposition looking to a departure from accepted methods must appeal to those who pay for the work, and then from an economic rather than a humanitarian standpoint. The manager of the mine may be interested in the physical condition of the men whom he employs, but his first care is usually on the financial side of the question. Men are usually easy to obtain; costs are usually hard to reduce.

Any radical departure from accepted standards, if it may hope for general, or even partial adoption, must show an improvement in one or more of the following aspects. A reduction in working costs; a larger percentage of ore recovered; a decrease in the amount of waste necessary to handle; an improvement in physical conditions; or a decrease in the danger involved. The first three of these conditions might be more properly included under one general heading of 'more economical ore extraction.' It is here proposed to consider a method which offers possibilities of advancement in not only one but in all of these conditions. It is not the purpose to present this as a complete discussion or as a method capable of immediate adoption, but rather as the foundation for more complete and extended investigation.

So far as I am aware the idea is original, yet it involves no new principles, only the application of old ones to different conditions. The increased use of power, together with a lowering in its cost of production and the development and perfection of rock-cutting machinery are two main factors which seem to render possible the adoption and use of the method to be described.

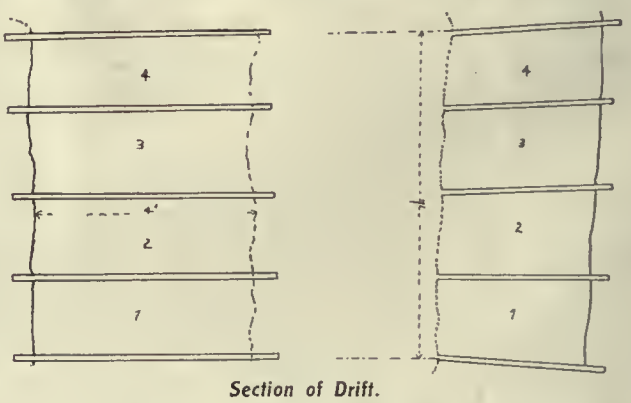
Driving or Tunneling.—The accompanying sketch represents in longitudinal section and plan the face of a 4 by 7-ft. drift, such as is ordinarily driven in development. In this case it is assumed that a 3-ft. round is to be broken and the rock removed from the face. The operation begins by cutting a channel at the bottom of the drift extending its full width, or as much wider as may be found necessary. This cut is made slightly deeper, say 6 in., than it is expected to break the ground. Following this the second channel is cut in similar manner at a distance above the first, depending on the character of the rock to be broken. After the completion of this channel, wedges are driven by pneumatic power into the second channel to break the block of ground between the two channels, which would have to be removed on account of the lack of space at the bottom of the drift. The amount of rock broken between the two channels would depend upon two factors; first, the character of the rock, and, second, the power of the pneumatic machinery employed in breaking. In the sketch it is assumed that five channels would be necessary for the whole breast, making the blocks each a little less than 21 in. thick. After the removal of the first block, the others follow in a similar manner, except that after the first block is removed it should be possible to insert a trolley or car under the succeeding blocks to catch the rock as it is broken. In this manner the shoveling of from one-half to three-fourths of the rock broken may be avoided, resulting in a material saving. In the driving of large tunnels several machines could be simultaneously employed and the percentage of rock that could be removed without shoveling could be greatly increased.

For a 4 by 7-ft. tunnel, as illustrated, from 60 to 85 sq. ft. of channeling would be necessary, depend-

ing upon the amount neeessary above the required dimensions. In driving in vein matter a seam will ordinarily be followed for one or both walls and present a line of weakness beyond which it would not be necessary to channel. In the sketeh it is assumed that the channels extend 6 in. into each wall, and this assumption gives the larger figures here quoted. These figures will form the basis for estimating the probable costs.

In shaft sinking it is assumed that at least two machines will be employed, one or more in each end of the shaft. The eentral block is in this case removed first and presents the most difficult part of the work, in that the rock must be removed as broken. After the removal of the eentral bloek the others follow toward the ends and are removed as broken. It is assumed that mucking and breaking will proceed simultaneously, so that the bottom of the shaft will be cleared for another round almost as soon as the preeeding one is broken. An interesting feature suggests itself in the possibility of avoiding a large proportion of the mueking by breaking the rock direetly into espeeially prepared receptaeles, whieh may then be hoisted a short distance and dumped direetly into the regular hoisting bucket or skip. As no blasting is done, timbers may be kept directly up to the faee and platforms provided for the placing of tools out of the way of the workmen. In blasting for a shaft the dimensions that will be broken are always uneertain, which results in the use of an excessive amount of timber and makes the operation of plaeing it diffieult and laborious. With the excavation eut to proper dimensions a considerable saving of blocking can be secured and a further saving in the labor of plaeing timbers, as well as a considerable saving in the amount of muck to be hoisted. For the breaking of a 3-ft. round, from 144 to 196 sq. ft. of ehanneling would be necessary under the conditions assumed for driving. With two machines in operation this would mean from 72 to 98 sq. ft. for eaeh maehine.

In raising but one machine is employed, and breaking begins in one end and proceeds toward the other. In this case some provision must be made to prevent the roek from striking the machine. In the breaking of the first blocks the channels are cut at such an angle as to cause the rock to fall to one side of the maehine, but when the last portion of the raise is reaehed it is not possible to aeeomplish this. On this aeeount the last portion is left until the next set-up and broken by cutting flat ehannels. The driving of a raise is always a difficult and expensive operation. Timbers are placed in position, usually to be broken by a sueceeding blast, ladders lose their rounds, machines are eonstantly being sent to the repair shop, hose is eut by falling roek, air-pipes broken, men quit on aeeount of bad air and hard work, and apparently all unwelcome eonditions whieh may be expected in any part of the mine are particularly concentrated in the driving of a raise. With the elimination of the use of explosives one of the neeessities of driving raises disappears, and where raises are desired for the bloeking out of ore, many of the disagreeable features of the operation can be avoided by the ehanneling process. In a raise 4½ by 10 ft., from 103 to 149 sq. ft. of channeling would be necessary, assuming the ehannels to be 2 ft. apart centre to centre. In breast stoping an 8-ft. breast is to be broken to a depth of 3 ft. The channels in this case are all inclined upward to allow of more ready removal of the cuttings. It is assumed that the limits of the orebody are defined by slips so that channeling outside of these boundaries is unneeessary. Whether breast, overhand, or underhand stoping be employed would be simply a matter of individual preference, and the adaptability of the machine used to any particular method of attack. In overhead work it would be necessary, as in raising, to incline the ehannels away from the vertical in order to allow the broken rock to fall clear of the maehine. In carrying an 8-ft. breast in a stope 6 ft. in width with channels 2 ft. apart, eentre to centre, 84 sq. ft. of channeling would be necessary to break to a depth of 3 ft. This assumes that the channels are eut to a depth of 3 ft. 6 in. and do not extend beyond the sides of ore broken. Thus 108 eu. ft. of ore would be broken or assuming 12 eu. ft. of ore in plaee to weigh one ton would give nine tons of ore.



Section of Drift.

In breaking rock by the ehanneling method the question naturally arises as to whether or not the roek broken would be of a size whieh eould be readily handled in the mine. If a block of rock 2 ft. thick, 3 ft. wide, and 4 ft. or more in length is broken out in one mass and allowed to fall down a stope or raise the result would undoubtedly be disastrous to any timbers which happened to be in the way. Such results are not to be antieipated, however. In breaking rock between channels by means of wedges and hammers the rock would be broken into fragments, the size of which could be largely controlled by the operator by varying the distanee between the channels, and particularly by varying the depth of ehanneling before inserting the breaking tools. For instanee, in the breaking of a 3-ft. round it is not necessary that a 3-ft. channel be completed before the breaking of the block begins. The channel may be made 1 ft. more or less in depth, the block of rock broken out, the ehanneling resumed, and this program repeated to the required depth. In this manner the size of the rock broken could be more readily controlled than it could by blasting.

In mining operations, and more particularly in tunnel work and shaft sinking the element of time is frequently of more importance than any other consideration. In this respect the channeling method

seems to offer possibilities which cannot be obtained by blasting. When a round of holes is shot in the breast the machinery employed in drilling must of necessity be removed to prevent injury by the blast, time must be allowed for the clearing of the atmosphere, the muck must be shoveled back from the breast, and the drills again set up before drilling can be resumed. Moreover, it is frequently found that the round of holes has not broken as anticipated, and a portion or all of the round has to be again blasted, resulting in more loss of time. On account of all of these conditions it is frequently found impossible in a 4 by 7-ft. tunnel to make an advance of more than 4 or 5 ft. in 24 hours even when three shifts are employed. In shaft sinking, provisions have to be made for handling timbers, tools, and men, and timbering must frequently be carried close to the bottom, and consequently it is constantly being broken or displaced. In the channeling method the necessity for removing the machinery disappears, and with it one of the most serious objections to the use of heavy machinery. If the machinery can be kept constantly in the breast, and can be manipulated by the use of power-driven appliances there is no material objection to any reasonable weight. The only problem that presents itself is that it be contained in a sufficiently small space to permit the expeditious removal of the muck. A machine capable of channeling 85 sq. ft. in an 8-hour shift and breaking the blocks as channeling proceeds does not seem impossible or even difficult to design and manufacture. Such a machine would give an advance of 3 ft. in 8 hours in a 4 by 7-ft. tunnel, or of 9 ft. in 24 hours. In a 6 by 12-ft. shaft two machines of the same power would give approximately the same results, and if the machines can be so designed as to operate in a space 3 ft. in width, it would be possible to use four machines, resulting in an increase of speed such as is impossible of attainment by the blasting method. The question of the removal of the muck would in this case be the most serious obstacle to rapid advance. To prevent the clouding of the atmosphere by dust some form of water attachment might be necessary for drilling uppers. For down-holes, or channels, water could be added in the usual manner.

Danger.—In underground work a large proportion of accidents is caused by falling rock, due to the effects of explosions of dynamite. Dynamite is therefore the prime cause of a large portion of accidents, whether from falling rock, premature explosion, or drilling into missed holes. If we dispense with dynamite, we eliminate the principal cause of accidents in underground work. A channeling machine is not a new nor an untried device. Such machines have been in use for years in quarrying and have been brought to a high degree of perfection. It only remains therefore to adapt the machine to underground conditions, adding to it other tools for wedging out the block of rock. Neither of these requirements seems difficult of accomplishment. As now manufactured, channeling machines are too cumbersome and unsuited in some respects for underground work. In the cutting of a channel across the face of a drift, for instance, it would be impracticable to maintain the channel at its proper width by simply moving the machine back and forth across the face. The wall of the drift would interfere, and besides provisions must be made for support of the machine. In my opinion the machine for the work will ultimately be a development of the air-hammer machine rather than a modification of the present channeling machines. Such machines have conclusively demonstrated their superiority in cutting capacity, low air consumption, and less massive construction over the reciprocating type of machine. It is true that they have not been successful for down holes without the use of water attachment, but in the case of a channeling machine the difficulty of removing the cuttings largely disappears. In any event the use of a water attachment is highly desirable and should be a compulsory requirement.

Following is a resumé of the qualifications which such a machine must possess: it must be sufficiently powerful to channel 100 sq. ft. in an 8-hour shift and break out the blocks; it must be substantially built to prevent the necessity of frequent repairs; it must be contained in as small a compass as possible; it must be capable of being readily and quickly changed in position; it should be provided with a water attachment for settling dust; and it must be simple of operation.

Data usually supplied by machine manufacturers give results for channeling varying from as low as 2 or 3c. per square foot to as high as 50 or 60c., depending on the character of rock and conditions of work. Average figures range between 10 and 20c. per square foot, including all costs of labor and power. These results are obtained under conditions differing from underground work, but with a proper machine the cost would be in the neighborhood of 16c. per square foot. Adding to this a cost of 4c. for breaking would give a total cost of 20c. per square foot. Under this assumption the cost for breaking rock in a 4 by 7-ft. drift would be from $4 to $5.67 per foot of advance. For a shaft 6 by 12 ft. under the same assumption the cost would be from $9 to $13 per foot of advance. For a raise 4½ by 10 ft. the cost would be from $6.87 to $9.93 per foot. These figures do not compare unfavorably with results obtained by blasting, even without taking into consideration the saving in timbers and mucking that would be effected. Figuring that in a 4 by 7-ft. drift two men would be required to operate a machine and that a 3-ft. round could be broken, the results obtained would be about as follows:

Two men at $3.50 to $4 per shift	$7.00 to	$8.00
Air at $4 to $5	4.00 "	5.00
Tool sharpening	0.50 "	1.00
Repairs, etc.	1.00 "	2.00
Total	$12.50 "	$16.00

These figures correspond closely to those obtained by assuming a cost of 20c. per square foot for channeling and breaking. All of these figures are confessedly little more than speculation with the data now available, but I believe them to be reasonable and possible of attainment, or even of reduction.

Calculations of a Copper Blast-Furnace Charge

By James A. Barr

*The problem is to select the best charge to smelt an ore containing SiO_2, 50%; Fe, 15; CaO, 10; S, 20; Cu, 5; gold 0.05 oz.; silver, 10.0 oz. under the following conditions: (1) furnace capacity 175 to 200 tons per 24 hours; (2) limestone close at hand; (3) iron ore must be shipped in 100 miles by railroad and contains no gold or silver; (4) coke obtainable at reasonable prices and of good quality.

Judging from the above conditions it would seem advisable to volatilize enough sulphur to make a converting grade of matte, to use as high a silica slag as is allowable by the size of the furnace, perhaps a sesqui-silicate, and substitute lime for the base as much as possible without making the slag too refractory. The table of slag formation temperatures shows that the lowest limit for iron is 21.6% without an undue rise in the temperature formation. The coke may be finally reduced on account of the sulphur available for fuel, but 14% should be used at first and reduced to the lowest possible limits with careful watching.

The methods of calculation are given in the following charge sheets and are performed in much the same manner as described in detail under the calculation of the lead charge. The data necessary for the computation are taken from the table and matter previously given.

CHARGE SHEET

Name of Ore	H_2O	Weight Wet	Weight Dry	Cu %	Cu wt.	SiO_2 %	SiO_2 wt.	Fe and Mn %	Fe and Mn wt.	CaO and MgO %	CaO and MgO wt.	S %	S wt.	
Copper Ore			475	5	24	50	238	15	71	10	48	20	95	
Limestone			400			10	40			50	200			
Iron Ore			100			10	10	60	60					
Coke	(140)					7.5	10	1	1	1	1	1	1	
			975		24		298		132		249		96	
					2		1/2 ash		12	in matte			83	loss
					22				120				13	to matte

*This may be increased to 1000 lb. by taking more copper, probably 485 pounds.

SLAG

	Per cent.
SiO_2	42.4
FeO	21.6 (Fe, 16.8%)
CaO	36.0
S	0.8
Cu	0.25

COKE (10% ash, 1.0% S)

Ash.	Per cent.
SiO_2	75.0
FeO	10.0
CaO	10.0

MATTE

	Per cent.
S	25
Cu + Fe	65
S (volatile)	80

FACTORS

$\frac{16.8}{42.4} = 0.4$ Fe factor.

$\frac{36.0}{42.4} = 0.85$ CaO factor.

SLAG LOSSES

$\frac{298}{0.424} = 704$ lb. slag, 0.25% of $704 = 2$ lb. Cu slagged.

$704 \times 0.008 = 6$ lb. S in slag.

$96 \times 0.80 = 77$ " " volatilized.

83 " " total loss.

MATTE COMPUTATIONS

$13 \div 0.25 = 52$ lb. of matte.

$(22 \div 52) \times 100 = 42.3\%$ Cu in matte.

$298 \times 0.4 = 119$ lb. Fe needed.

120 " " present.

1 " " excess.

AVAILABLE IRON

$65 - 42.3\% = 22.7\%$ Fe in matte.

$52 \times 0.227 = 12$ lb. Fe in matte.

$298 \times 0.84 = 250$ lb. CaO needed.

249 " " present.

1 " " lacking.

These figures are near enough, but larger amounts should be corrected as done in the Lead Charge Sheet.

MATTE FALL

$\frac{52}{975} \times 100 = 5.3\%$ matte fall.

This is low and might well be increased at the expense of lowering the grade of matte.

Remarks.—If the corrections in the fluxes amount to much in the first estimate, say over 10 lb., the calculations should be gone over again. The charge may be increased to any quantity by multiplying all of the constituents by the necessary factor.

APPLICATION OF SLAG DATA

Since the basic problem is to select the best charge or slag to smelt a given ore or selection of ores, whether it is done for comparison of two methods or to determine the most economical slag, all resolve into the question, what mixture put into the furnace will yield the greatest net profit.

Example.—Given a collection of ores and fluxes whose analyses are given in the following tables:

	SiO_2, per cent.	FeMn, per cent.	CaOMgO, per cent	S, per cent.	Pb, per cent.	Cu, per cent.	Au, oz.	Ag, oz.
Lead ore	16	..	10	10	60	2	..	50
Silicious flux or ore	70	4	..	4	..	..	1	..
Irony ore	10	60	..	..	..	..	..	..
Limestone	3	..	54	..	..	..	..	..
Coke ash, 10% coke.	75	18	9	..	..	..	..	..

The lead ore is the one to be primarily considered, it being the output of the mine in question. The charge against this ore delivered at the smelter bins is $2 per ton. The silicious ore or flux may be readily obtained as a custom ore and a treatment charge of $6 per ton imposed, returning 95% of the metals to the seller. Limestone costs 75c. per ton delivered from the company's quarry, and irony ore costs $4 delivered at the smelter. First decide if any of the ores should be roasted. The only ore with an appreciable amount of sulphur is the galena. The one very prominent argument in favor of not roast-

*Abstract from 'Testing for Metallurgical Processes.' Published by the *Mining and Scientific Press.*

ing is its high silver content. Since one unit of sulphur costs 25c. to handle, then in one ton of galena would be the following costs if not roasted:

10 units of sulphur at 25c. $2.50 per ton.

Charges if roasted.	Per ton.
Roasting H. & H.	$1.76
Losses Pb, 4% of 1200 lb., at 1c*	0.48
Losses Ag, 4% of 50 oz., at 50c	1.00
4 units of sulphur left, at 25c	1.00
Total	$4.24

*The 1c. equals net profit that would ultimately be obtained if one pound of metal were recovered as market lead.

Difference in favor of not roasting, $1.74 per ton. This does not take into account any benefits from the use of a sintered H. & H. product. From the charge-sheet may be taken the quantities of ore and flux making up one ton of blast-furnace mixture and figures of profit and loss determined as follows:

PER TON OF CHARGE*

Recovery, Pb 93%, Ag 95%, Au 98%.

CHARGES

0.21 tons limestone, at 75c	$0.16
0.32 tons irony ore, at $4	1.28
0.16 tons lead ore, at $2	0.32
Refining 0.046 tons base bullion, at $12†	0.55
Smelting 1 ton charge, at $3	3.00
Total charges	$5.31

*These figures are taken from the lead charge sheet.

†The cost of refining is assumed to cover the cost of placing all the metals in marketable shape.

RECOVERY

192 lb. Pb, at 4c‡	$7.68
7.6 oz. Ag, at 50c	3.80
Custom ore, 0.27 ton, at $6	1.62
Total recovery	$12.10
Charges	5.31
Profit	$6.79

‡Does not include freight to market.

Next the charge may be calculated with a different slag and estimates made of the profit with the more basic or acid type. Here inaccuracies creep in because, with the data available, it is not possible to determine exactly the decreased cost for smelting one ton of charge when using a faster running slag or to estimate without actual experiment the difference in the recovery of the metals. The cost computations are repeated with the new slag and the resulting net profit compared with the previous results and deductions drawn.

It will be noted that the gold content of the siliceous ore is neither charged nor credited to the furnace charge. This will introduce a slight inaccuracy because this omission is based on the assumption that the recovery of the gold will only be the 95% which is returned to the ore seller. Since the recovery of gold is given as 98% there will be a difference of 3% in favor of the recovery, or about 16c. in this case, which is well within the limits of errors for the example.

Sixty years ago Overman, in his treatise on metallurgy, said that successful smelting was merely a study of slags.

GEOLOGICAL MAP FOR ARGENTINA

The Argentine Government being engaged in the construction and operation of railways where the climate and water resources resemble those of the southwestern United States, has met with grave difficulties in getting sufficient and proper supplies of water. Engines imported at great expense and put in operation on western roads of the country have become useless after a very brief service, and as the railways are being extended in Patagonia, further difficulty from this source is anticipated. Our Minister to Argentina, Charles H. Sherrill, saw in these circumstances an opportunity to extend a helping hand and called the attention of the able and progressive Minister of Public Works, Ramos Mexia, to the work of the U. S. Geological Survey and Reclamation Service. A plan for topographical and geological surveys, of the kind necessary to reasonable prediction of the occurrence of artesian waters, was prepared at the request of the Minister of Public Works by Bailey Willis of the U. S. Geological Survey, which, having been adopted, is to be carried out by Mr. Willis with the assistance of American topographers and geologists. The work is undertaken under a definite contract which runs for two years, and is independent of the Bureau of Geology and Mines which has been maintained for some time by the Argentine Government under the Department of Agriculture. This Bureau is manned chiefly by German geologists under the direction of an eminent Argentine, Señor Hermitte. It has done a large amount of excellent work in geologic exploration, but the results have been of comparatively little value because there are no topographic maps upon which to present the facts. It is expected that the surveys to be carried out under the Minister of Public Works will result in topographic and geologic maps of extensive areas. The first year's work has already been laid out in the neighborhood of the 41st parallel, south latitude, along the line of a railway which is being built from Puerto San Antonio to Lake Nahuel Huapi in the Andes. It will comprise not only the line of the road, but the territory on both sides of it to a considerable distance.

THE DIVINING ROD

In speaking of the divining rod Myron L. Fuller, in Water-Supply Paper No. 255 of the United States Geological Survey, says, "No appliance, either mechanical or electrical, has yet been devised that will detect water in places where plain common sense will not show its presence just as well. The uselessness of the divining rod is indicated by the facts that it may be worked at will by the operator, that he fails to detect strong water currents in tunnels and other free courses that afford no surface indications of water, and that his locations in regions where water flows in well defined channels are no more successful than mere guesses." The report can be obtained without charge by applying to the Director of the United States Geological Survey at Washington.

The Clays of Tennessee

By George H. Ashley*

An examination of the clays of west Tennessee, now being made by the State Geological Survey, has already convinced the State geologist that Tennessee offers exceptional opportunities for the development of a large industry in the manufacture of china-ware, sanitary and porcelain-ware of all kinds, glazed and encaustic tile, electric high-tension insulators and fire-brick, to say nothing of the great number of lower-grade products—ornamental, paving, and common brick, terra cotta, roofing, and drain-tile, and domestic ware. At the present time the State produces between one and two million dollars worth of clay products; mostly in the form of common building brick. It is in the manufacture of the higher-grade products that the State geologist believes there is room for great expansion. In the first place, the State has the necessary raw materials. Tennessee clays are being shipped in large quantities to Indiana, Ohio, Pennsylvania, and New York, in many cases supplying the largest part of the raw clay used.

In the second place, south, west, and southwest of Tennessee lies a great market at present obtaining its supplies from States to the north and east of that State, the raw materials being shipped from Tennessee to the potteries, manufactured and shipped back again to the State, or through it on its way southwest. In the third place, Tennessee is well supplied with shipping facilities, both by rail and water. To take a singe illustration: in 1891 a pottery was started in Evansville, Indiana, making semi-porcelain and white-granite table-wares. It uses ball-clay from Tennessee, kaolin from North Carolina and Georgia, feldspar from Pennsylvania, and ground flint from East St. Louis. In 1904 the output of that plant alone had grown to an annual value of $220,000 and gave employment to 300 hands.

Portions of west Tennessee are already dotted with great holes from which clays are being shipped. The clay beds range in thickness from 2 ft. or less to 18 ft. or more, sometimes in solid beds of uniform character, sometimes in a succession of beds of varying character, the individual beds being suitable for distinct uses. Thus, one bed may be especially suited to the making of saggars, the next underlying bed for white china-ware, the next for high-tension electric insulators, etc. As a rule the deposits are limited in extent to a few acres, but as a bed of clay ten feet thick and ten acres in extent will yield over 200,000 tons of dry clay, these little pockets in the aggregate could supply a large output, as indeed they are doing at present. As a rule the deposits have a rather heavy overburden, amounting, in some cases, to 30 or 40 ft., though the average for the pits now being worked will probably not run over 15 or 20 feet.

Apparently the main obstacle in the past to the establishment of clay plants in west Tennessee for the manufacture of high-grade wares has been the lack of trained labor, and the fact that the nearest coals, those from the west Kentucky fields, are too high in sulphur. It is probably true that a plant starting in that territory would have to import a certain amount of skilled labor. As the belt through which the best clays run follows the high divide between the Tennessee and Mississippi rivers—a region of fine farms, prosperous towns, rapid streams, and excellent health conditions, equal in those respects to most parts of Ohio, Indiana, and Illinois, the importation of such labor should present no difficulties. The fuel problem may be met by converting the coal into producer-gas and washing; by the use of oil from the neighboring Caddo oilfield, by the possible use of producer-gas from the beds of lignite found in the same region, or by the use of coal from east Tennessee. In the latter case it would require the bringing in of only coal enough for the kilns, as Kentucky coal could be used for power for the mills. Or the plants could be built at Nashville or some other middle Tennessee point within easy reach of the ball-clay from west Tennessee, the kaolin and feldspar from Georgia (if Tennessee deposits prove insufficient), and coal from the coalfield just east of the city. Nashville is naturally a distributing point with both rail and water facilities, and already has an encaustic-tile plant and other large clay interests. Considering, therefore, that the bulk of the raw materials of all kinds used in the manufacture of high-grade clay-wares is obtained from the South, it would seem that as much of those wares as may be needed to supply the Southern and Southwestern market could well be made there.

*State geologist of Tennessee.

The Mother Lode in California extends from the southern end of Mariposa county near the old village of Bridgeport to the northern part of El Dorado county. It is not a continuous vein or lode, but occurs as a series of nearly parallel veins or lodes, for most part with frequent, and in some instances, long interruptions within which no characteristic vein or lode occurs. The formations through which this great gold-bearing belt occurs are various. There are clay slates, ancient greenstone tuffs, and in a few places massive greenstone, both diorite and diabase; granitic rocks, serpentine, and much amphibolite-schist, the last a result of the alteration of the greenstones and greenstone tuffs. In some localities there are large zones of ankerite, a combination of carbonates of lime, magnesia, and iron. This material is occasionally found gold bearing, but with few exceptions only slightly so. A remarkable exception was found in the Rawhide mine in Tuolumne county, where the ankerite was found extremely rich, some of it milling $20,000 per ton.

Pyritic smelting was successfully practised at Mansfield many years since. It was first introduced into the United States on a large and successful basis by the late F. R. Carpenter at Deadwood, South Dakota, in the Deadwood & Delaware smelter, though small plants had previously been operated with indifferent success at Leadville and elsewhere.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Superficial Indications of Ore-Shoots in Depth

The Editor:

Sir—The contribution by William H. Storms in the issue of the *Mining and Scientific Press* of October 22, entitled 'Superficial Indications of Ore-Shoots in Depth,' has interested me greatly, as I had never before seen the subject discussed in print, or at least presented in such form. To me it seems that the gist of the whole article is contained in the first half dozen lines of his second conclusion, which reads: "Gulches or natural depressions crossing the strike of the lode, or vein, are the physical expression of disturbances beneath the surface, and it is rarely, if ever, that an ore-shoot will be found to extend from solid unbroken ground beyond such surface evidence of disturbance." I cannot recall in many years of mining experience where these 'rules' of Mr. Storms do not apply. It is a subject of great importance to the miner, and of earnest thought for the geologist, and I am surprised that there has not been some discussion of the matter heretofore.

I do not think it sufficient to say that I agree with all that was said by Mr. Storms, and let it go at that. The condition described is an effect, and it would be interesting to know the cause. If a gulch is an indication of disturbance occurring subsequent to the formation of an ore-shoot, the miner wants to know where and how to look for the lost portion of the faulted orebody. The region of disturbance beneath the surface where exposed by mine workings should be studied more closely with a view to ascertaining the direction of movement along the fault-plane. This knowledge would greatly facilitate the re-discovery of the lost ore-shoot. It is also possible that some gulches were not caused by disturbance beneath the surface, being the result of erosion alone. I may cite an instance of this kind occurring in the San Domingo gravel mine in Calaveras county, California, where a washed-out section of the channel exposes a line of fracture, or fault, showing the up-stream side of the bedrock to be from 4 to 6 ft. lower than that on the other side of the fault. The movement was vertical, as shown by the striations on the rock-walls of the fault. The fault extended up through the gravel to the surface, which where exposed was 50 ft. or more in height, proving that the disturbance occurred after the gravel was deposited. This fault-line can be traced several hundred yards to where it enters a gulch at an acute angle, and continues on up the gulch. The exposures on this line of disturbance indicate that the gulch above the point where the fault enters is on a line of disturbance, but below the place where the fault enters the gulch the latter is due entirely to erosion, the gravel having formed a dam there and caused the water in the gulch to cut a different channel.

To apply the 'rules' to the prospective development of an ore-shoot which apparently crosses a gulch, it would be necessary first to determine whether the gulch was caused by a disturbance beneath the surface, or whether it was merely the result of erosion. The miner, as quickly as he gets below the surface, can hardly go a foot without encountering a seam or fracture of some kind. These we may call 'geological letters'; next he meets with larger slips and faults, which may be considered as 'geological words'; later he finds a horse, or runs against a dike, or some different kind of rock—the 'geological sentences.' These are the practical lessons to be learned by the miner as he toils slowly through the mountain. The article by Mr. Storms points toward an important geological lesson, and by collecting a few letters and words from the miners, and a few sentences from the geologists, and putting them in their proper places, something of value will undoubtedly be learned.

H. P. GORDON.

Oakland, California, November 19.

A Joke

The Editor:

Sir—The United States Civil Service announces an examination on December 7, 1910, to secure eligibles from which to make certification to fill vacancies as they may occur in the positions of mineral examiner in the Forest Service at $1800 per year.

We laugh at the development company that nowadays does not get the best expert advice about the orebodies it is developing or searching for. To neglect the study of faults, dikes, intrusions, occurrence of the ore, and even the mineral associations found in the ore and the gangue is as inexcusable today as is smelting by principles of guesswork instead of chemistry.

In selecting men for the important position of mineral examiner for the Forest Service, a man who has the say whether an entire region is to be opened up to exploitation and development, or to be locked up by a paternal government, we should expect the government to pick out the most talented experts, and for special regions to use men who have studied these regions. In deciding the possible mineral character of a district like the Mother Lode, who would be better fitted than Waldemar Lindgren or F. L. Ransome? J. E. Spurr, George H. Garrey, or S. F. Emmons know much of the rich late Tertiary type of gold deposits of Nevada and the West. In Arizona to decide on a probable mineral region, one must have studied the many varieties of limestone orebodies and their relations to intrusions and the structure of the country. If a disseminated copper deposit is inspected, much can be told from a field and then a microscopic study of the leached surface rock, etc.

To properly discharge its duty, the Forest Service cannot afford to get any but the best men for this work, regardless of the cost. Hence the joke mentioned at the top of this communication lies in the

following list of subjects on which the applicant will be examined:

Subjects.	Weights.
1. Spelling (twenty words of more than average difficulty)	5
2. Arithmetic (fundamental rules, fractions, percentage, interest, discount, analysis, and statement of simple accounts)	15
3. Penmanship (the handwriting of the competitor in the subject of report writing will be considered with special reference to the elements of legibility, rapidity, neatness, general appearance, etc.)	5
4. Report writing (test in writing in letter form a report of from 150 to 200 words in length, summarizing and arranging in logical order a series of facts included in a given statement of 400 to 500 words)	10
5. Practical questions (including surveying)	35
6. Training and experience	30
Total	100

Red Tape

The Editor:

Sir—Six months' wallowing in a succotash of certificates and affidavits had weakened the engineer's mind. Too stupefied to realize that all the regulations had been complied with, that the task was completed, and all the drawings and papers were ready for filing, his tired mind wandered on until it brought forth this final oath.

Let us hope it relieved the strain, saved him from the asylum, and that the Forest Service will not return it for correction.

(Final miscellaneous oath) 'EXHIBIT Q'

APPLICATION FOR RIGHTS OF WAY IN THE NATIONAL FORESTS

By the

Middle Pacific Hydroelectric Power Company

STATE OF CALIFORNIA, } s.s.
COUNTY OF NEVADA }

Exhausted Smith, being duly sworn, says that he is president of the Middle Pacific Hydroelectric Power Company, and no other; that he is chief engineer of the Middle Pacific Hydroelectric Power Company, and no other; that he is both president and chief engineer of the Middle Pacific Hydroelectric Power Company, and no other; that as president and chief engineer of the Middle Pacific Hydroelectric Power Company, and no other, he has sworn to all, the all and singular, multitudinous, and multiplied, and no other, certificates, affidavits, and affirmations, respectively, in triplicate, on all and singular, maps, field notes, drawings, details, sheets, specifications, and representations, whatsoever, stated or implied, in the accompanying documents herewith, respectively, marked 'Exhibit A,' 'Exhibit B,' 'Exhibit C,' etc., including 'Z,' and no other.

AND FURTHER the affiant, as an ordinary man, sweareth yet.

IN WITNESS WHEREOF I have hereunto set my hand and the corporate seal of Middle Pacific Hydroelectric Power Company this 15th day of November 1910.

EXHAUSTED SMITH,
President and Chief Engineer,
Middle Pacific Hydroelectric Power Company.

Attest.

SUBMIT JONES, Secretary,
Middle Pacific Hydroelectric Power Company.

[SEAL]
of the Middle Pacific
Hydroelectric Power Company.

Avino Mines Company

The Editor:

Sir—In Ralph Nichols' contribution of October 21, published in your issue of November 5, he refers to the unsatisfactory results obtained from concentrating Avino ores. I believe that the trouble was due to the presence of tetrahedrite in the ore. This was the main carrier of the silver, and in the process of grinding, this mineral slimed and was carried off in the tailing. The concentration aside from this was good, all of the baser minerals being saved without any trouble. This difficulty of concentrating an ore containing tetrahedrite is well known, and has led to difficulties in other districts. I believe that at the Comet mine, at Basin, Montana, similar difficulty was encountered.

It was for this reason, at Avino, that recourse was had to lixiviation, which was carried on very successfully by Nick Flynn, who is now metallurgist for the Arizona Copper Co., at Clifton, Arizona.

J. PARKE CHANNING.

New York, November 11.

An Explanation Wanted

The Editor:

Sir—I have tried to frame a reply to 'An Explanation Wanted' but cannot do it without impugning I. A. Jackson's statements.

1. No mention is made of lime or other alkali used or required.

2. Does 'arsenical sulphide' mean sulphide of arsenic or arsenical pyrite?

3. Does the term 'lead oxide and shavings' mean lead shavings or zinc shavings?

4. Where was it ever customary to use alternate leachings of strong and weak solutions?

One would naturally conclude that the lead oxide removed sulphide from the solution, but the description of the condition of the zinc points to mercury in the solution. If there was sulphide in solution, there could not be any mercury, and *vice versa*.

A 94% extraction from $6 tailing containing 33⅓% of slime, in 96 hours by leaching, is truly an astonishing result. I pass!

CASEY WHYE.

Cyanide Problem

The Editor:

Sir—In the letter from Lee Fraser appearing in your issue of October 22 he refers to certain practice in Borneo as having been under my direction. I may have described the practice referred to, but credit for it should be ascribed to Reg. H. Parole, the general manager for the company, and to H. S. Young, in charge at Bau.

ALFRED JAMES.

New York, November 1.

Guides in some mines, notably those of the Butte district, Montana, are made of oak, instead of pine as is the case nearly everywhere else. It is claimed that the oak, being stronger and firmer than the softer woods, affords greater security in the event of the falling of a cage or skip.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A hand-jig was described in the issue of the *Mining and Scientific Press* of November 2, 1907, a copy of which may be had by sending 25c. in stamps.

Tailing and sulphide concentrate may be elevated by means of a hydraulic elevator. Sand tailing can, of course, be more readily lifted than sulphide, owing to difference in specific gravity of the two materials.

Power for the ordinary modern stamp-mill is generally calculated on a basis of 2½ hp. per stamp. This includes rock-breakers, stamps, concentrators, clean-up barrel, and any other machinery not out of the ordinary.

Mining and all other corporation stocks in California are assessable whether the company be organized on a non-assessable basis or not. Under California laws there is legally no such thing as non-assessable stock.

Tinstone (cassiterite) of remarkable purity occurs on the San Jacinto estate, in the Cajalco mine, in Riverside county, California. This occurrence is four miles in a southeasterly direction from the city of Corona, and is the only authenticated occurrence of tin in southern California, though it may possibly exist elsewhere in that vicinity.

Hoisting-ropes are subjected to the most severe strain when the skip, bucket, or cage is stopped quickly. At such time the rope has not only to carry the dead load, but must also be strong enough to meet the momentum of the moving load. Hoisting engines should never be started or stopped quickly. A careful engineer understands this and avoids it as far as possible.

The compressive strength of timbers is seldom considered by miners. They generally select such timbers as experience has taught them will answer the purpose for the time being. They have also learned that no amount of timber can hold up a mountain when the ground begins to work. It is seldom a cave can be averted after heavy ground starts. It is then usually too late to employ additional timbers.

Substantial tracks in mines are a good investment. Heavier track in the first cost is somewhat greater, but the saving in repairs on cars, and in the loss of time in refilling overturned cars, and replacing derailed cars on the track soon compensate for the increased cost of good tracks and switches. T rail of 24 lb. is sufficiently heavy for ton cars, and if tramming be done by hand 16 lb. per yard is heavy enough.

Wulfenite occurs in many of the quartz veins of the Southwest desert regions. This mineral is lead molybdate. Probably no mineral is more frequently mistaken for gold when discovered in panning. The old-time desert prospector, to use a popular phrase, 'is onto' this deceptive 'color,' and is at once able to distinguish between gold and wulfenite. A few drops of hydrochloric acid will destroy the illusion. The mineral fuses readily to metallic lead before the blow-pipe.

Azurite is copper carbonate. It has a beautiful blue color. Linarite, a basic sulphate of lead and copper, and vivianite, a hydrous phosphate of iron, have also each a beautiful blue color. Glaucophane is a blue variety of hornblende. Frequently when azurite occurs in an ore, miners refer to it as 'bromide of silver.' No silver bromide, or chloro-bromide is blue, all being of a yellowish, greenish, or greenish yellow color. The error above referred to is probably due to the occurrence of azurite with some chloride silver ores, common in Mexico.

Hydrometers are based on the general theory of the variable immersion of the instrument in liquids of different density. The Baumé hydrometer is graduated by immersion in two liquids—water and salt water containing 15% of salt of a density 1.11383 at 17.8°C. The division to which the hydrometer sinks in the salt water is marked 15. For liquids lighter than water (petroleum) the zero scale is placed near the bottom of the straight stem. It is placed at a point to which the instrument sinks in a 10% salt solution. The point to which it sinks in water is marked 10.

Lead and copper sulphide ore may be smelted together in a lead blast-furnace with proper fluxes and fuel. The lead will collect in the bottom of the crucible, while the copper unites with the sulphur to form matte which accumulates in a layer immediately on top of the molten lead, the slag occupying a higher zone. The lead passes through the siphon to the well, where it is either tapped or ladled out; the matte is drawn off through a tap-hole just above the level of the molten lead, and the slag is run out at the proper level above the matte. If the matte be very low grade it may be re-smelted or blown up in a converter to the desired grade.

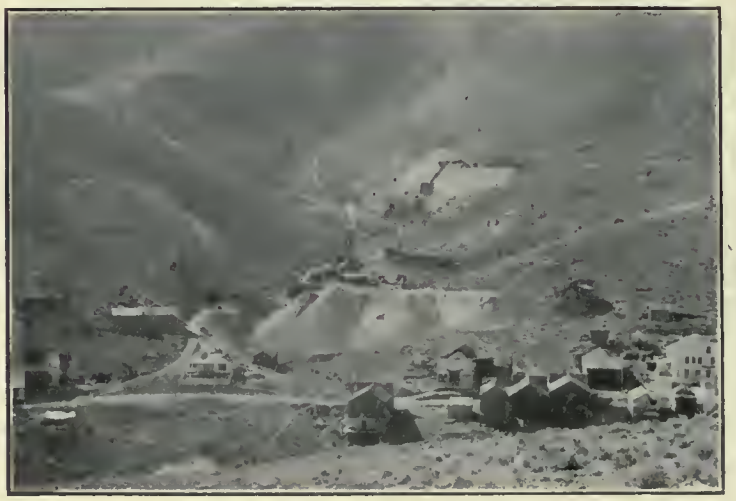
The cost of stripping the overburden from ore deposits or gravel depends upon many factors. In the case of gravel, if a stream of water under pressure is available, the overburden may be hydraulicked off at a cost of 3 or 4c. per ton. Soft rock and earth may sometimes be hydraulicked at low cost, but where the rock is firm and even moderately hard it must be blasted before removal. In case there is a large amount to be taken off, it will usually pay to run a drift into the rock with a cross-heading. This excavation is then charged with several tons of 'low powder,' the quantity depending on the amount of work done. When the blast is fired the rock is broken into pieces small enough to be removed by steam-shovels, and these are employed on large jobs, for the reason that it is the most economical. Removing rock with wheelbarrows or even hand-trammed cars is more expensive, but in small operations they are employed because the work to be done does not justify the expense of the steam-shovel installation.

Special Correspondence

SEVEN TROUGHS, NEVADA

Development and Operation of Gold-Silver Mines in Humboldt County.

Seven Troughs district is situated 30 miles northwest of Lovelock, Nevada, on the east slope of Seven Troughs mountains, and embraces an area 13 miles in length and 4 miles in width, which is drained by Stonehouse, Burnt, Wildhorse, and Seven Troughs canyons, all running easterly and opening into Sage valley. The one farthest north is Stonehouse, where the little mining settlement of Farrell is situated. Seven Troughs canyon, which is the most southerly, has been and is now the centre of the greatest mining activity. At the lower end of this canyon is the town of Mazuma, where there are two mills, of which one is in operation; a mile or farther up the canyon is the town of Seven Troughs, close to which are the Mazuma Hills and Kindergarten mines; Vernon, another small town of the district, is situated 2½ miles south of Mazuma. The mineralized belt, of the length and width above given, in which the veins occur, trends nearly north-south and consists of andesite and rhyolite, traversing which are dikes of basalt. In the vicinity of Seven Troughs are the Mazuma Hills, Reagan, and Kindergarten veins. The first two have been opened on the Mazuma Hills group on the north side of the canyon; they have nearly a north-south strike. The Kindergarten vein, opened on the Kindergarten group which lies on the south side of the canyon, has nearly an east-west strike and a dip of 35° south. The gangue material in these veins consists of quartz, calcite, talc, and altered wall-rock.



Seven Troughs, Nevada, Showing Kindergarten Mines and Tyler Lease.

The Seven Troughs Coalition Mines Co., having six claims, including what was originally the Kindergarten, Wihuja, and Therien groups, has opened the Kindergarten vein by a 575-ft. incline shaft, 500 ft. of which follows the dip of the vein. There are five stations, from each of which a level has been driven on the vein, in opposite directions from the shaft. The vein is 3 ft. wide. A vertical shaft, situated 340 ft. southeast of the incline, was sunk some time ago; this cut the Kindergarten vein at a depth of 300 ft. Nearly equal tonnages of ore are hoisted daily from the two shafts. The development, including the shafts, cross-cuts, and drifts on the vein, aggregates close to 3000 ft. A cross-cut is being driven from the 400-ft. level to intersect the Mazuma Hills and Reagan veins, which are known to extend south into this group. The incline shaft is equipped with a steam plant, fuel oil being used. The amount of ore being mined and milled, though comparatively small, is said to run about $150 per ton. Small lots of very rich ore have been sacked and shipped. Some remarkably rich and showy specimens are obtained in this mine. The mill has 10 stamps, amalgamating plates, and concentrating tables, and a recovery of 90% is said to be made. The tailing is impounded, with the idea of treating it by cyanide later. The manager for this company is L. A. Friedman, with W. A. Ellithorpe and W. J. Thomson as mine and mill superintendents, respectively. There are 85 men on the property, including 20 men employed by three sets of lessees. The Engineer's lease, running to H. C. Zulch, W. T. P. Maeder, and J. Scarlett, is yielding a small tonnage of high-grade ore which is treated at the company's mill; the Cole lease is being operated and the output is disposed of in similar manner. The Tyler lease runs to the Lookout M. Co., for which Fred L. Tyler is manager, This takes in a block of ground 600 by 600 ft. on the Coalition company's group, higher on the hillside and southwest of the Kindergarten proper. Here a 2-compartment vertical shaft has been sunk 422 ft. It is well timbered, is in good order, and is equipped with a steel head-frame. A gasoline engine is used in hoisting. This shaft cuts the Kindergarten vein on its dip at the 422-ft. station, from which drifts run 300 ft. in ore on a vein 3 to 8 ft. wide. The hanging wall is brecciated, the foot-wall is andesite; the dip of the vein is apparently 30° south. The ore consists of quartz, talc, and wall-rock, carrying considerable sulphide of iron. One lot of 44 tons of ore taken from this level milled $26 per ton. Some ore is being stoped that is said to run $45 per ton. By driving a cross-cut from the bottom of this shaft the Mazuma Hills vein is to be tapped. Work on this cross-cut has been commenced. Mr. Tyler anticipates getting a good body of ore in the latter vein. There are two more years remaining under the terms of this lease. A force of 12 men is employed. Water for boilers and for the mill is pumped from the old Sandifer shaft in the bed of the canyon. Some is also obtained from the Tyler shaft. The Mazuma Hills and Reagan mines, belonging to the Mazuma Hills M. Co., have been idle for a year, owing to disagreement among stockholders. These properties are well developed, and are said to have good ore reserves. One of the company's assets consists of a 10-stamp mill at Mazuma. The mines were being sampled by outside people about November 1, and reports were current that they might soon be taken over by another company.

The Darby Ore Reduction Co. has a modern milling plant at Mazuma, which is being operated principally on ore taken from the Florence mine, situated half way between Seven trough and Vernon. The Florence belongs to the Seven Troughs M. Co., and is under lease to the Darby company. This mill is operated by gasoline engines and has a Scully No. 3 crusher and two 5-stamp batteries. The pulp passes from the mortars over plates, and thence to Deister tables, 2 for coarse material and 2 for slime. The sand and slime are separated by a Dorr classifier. The sand is pulverized in a tube-mill, the product of which is raised by a Frenier pump to a second series of amalgamating plates. The entire tailing of the mill, thus reduced to slime, passes to the cyanide plant, where it is subjected to cyanide treatment in agitating tanks, then filtered by the Oliver continuous method. The ore received is mined from the two veins of the Florence, gold predominating in one and silver in the other. The ore from the former contains free gold and some silver; that from the latter contains tetrahedrite, and ruby silver. The gangue consists of quartz and baryte. The concentrate runs high in silver, also in copper, derived from the tetrahedrite. This company employs 50 men at mine and mill. Matthew Gillespie is manager.

The Fresuo Development Co. is having important work done in Wildhorse canyon, under direction of John McGivney. This group is a mile northeast of the Mazuma Hills, and is on what is known as the lower zone of the principal mineral belt. A 320-ft. vertical, 2-compartment shaft has been sunk. The surface equipment includes a steel head-frame and a 25-hp. gasoline hoist. A level was driven

on the vein from the 40-ft. station, gaining depth rapidly as it follows the vein into the body of the mountain. Another level has been run on the same vein from the 300-ft. station. This work shows the vein to be 6 ft. in width, one wall being andesite and the other basalt. It is known as the Wild Bull vein, the ore from which contains free gold and gold and silver in sulphide. A second vein was opened by driving a 120-ft. cross-cut from the 200-ft. station of the same shaft. There are 14 men on the payroll. Between the Mazuma Hills and the Fresno is the Providence Extension, a group which is being developed by Morris, Illinois, operators, whose work is in charge of M. J. Whelan. By some surface work and shaft sinking, Mr. Whelan believes he has opened the veins of the Mazuma system, and

Mill of Darby Ore Reduction Co., Mazuma, Nevada.

it is planned to sink to a depth of 500 ft. and explore from the shaft. A 25-hp. gasoline engine is to be installed. In the same locality are the Eclipse and Providence, on which a large amount of development has been done. The Mammoth group, two miles west of Farrell, belonging to Otis Johnson and others, has high-grade gold ore in a quartz vein. This discovery is on the west side of the belt, close to the granite. It is estimated that there are 200 to 250 men employed at the mines, mills, and prospects of Seven Troughs district. Late reports are to the effect that the Mazuma Hills mines have been taken under a three-years lease to the Darby Gold Reduction Co., with an option on the control of the stock.

PANAMA

Annual Session of American Institute of Mining Engineers.—Interesting Lectures on Mine Fires.

Aboard ship and on the broad Atlantic is somewhat an unusual place for holding the sessions of the American Institute of Mining Engineers, but it has the advantage of not having rival attractions and assures a good attendance at the meetings. The ninety-ninth meeting of the Institute was supposed to be held in the Canal Zone from November 1 to 8, and, as announced in the circulars, the entire passenger accommodations of the Hamburg-American steamer, the *Prinz August Wilhelm*, were secured for the members attending the meeting. When the ship sailed from New York on the morning of Friday, October 21, every stateroom was taken, and even some of the officers' quarters were pressed into the passenger service. The arrangements for the trip had been made by Joseph Struthers, assisted by A. E. Vaughan, and were perfect. Their efforts were aided by a Providential dispensation in the form of magnificent weather. The party sailed from New York under cloudy skies, with heavy wraps not uncomfortable, and for the first 24 hours the sea, still slightly rough from the fag ends of the hurricane of a few days before, gave some discomfort to a few of the party whose stomachs were unacclimated. By Saturday afternoon the skies had cleared, and from then until the arrival at Colon, on Tuesday, November 1, the weather was all that could be desired, clear, but naturally growing warmer as the tropics were approached. The first two days were given up to getting settled and becoming acquainted. On Sunday, the third day out, services were held in the social saloon, with a sermon by Dr. R. W. Raymond, secretary of the Institute. In the afternoon Dr. Raymond gave an interesting talk on Jamaica, that island being on the itinerary of the trip.

The first session of the Institute was held in the saloon at 2:30 o'clock on the afternoon of Monday, October 24. It was called to order by D. W. Brunton, president of the Institute, and was devoted to the discussion of fighting mine fires. It was entirely informal and the papers, or rather 'talks', were not included in the list of papers announced for the meeting. The *piece de resistance* and the first talk of the session, was a description of the method adopted by the Lehigh Coal & Navigation Co. in walling off the fire at the Summit Hill mine. It was presented, with blackboard illustrations, by W. A. Lathrop, president of the company, who devised and successfully carried out the stopping of the progress of this fire which had resisted all previous efforts since it started in 1859. Mr. Lathrop was followed by S. D. Warriner of Wilkesbarre, Pa., who told of extinguishing the fire in No. 8 shaft of the Calumet & Hecla copper mine at Houghton, Mich. This fire occurred in 1900 and took two months to extinguish. Other informal but interesting talks were by R. V. Norris, of Wilkesbarre, on the fire in the Big Lick slope of the Lykens Valley Coal Co., near Lykens, in 1901, which was extinguished in 1903, a strike of miners intervening and allowing the fire to gain headway; and by W. J. Richards on the final conquering of the fire in the Pine Knot colliery in the Heckscherville valley, three miles from Pottsville. This fire started in 1866 and was put out in 1905. These four men, by the way, Messrs. Lathrop, Richards, Warriner, and Norris, represent anthracite companies whose combined tonnage exceeds 50 per cent of the total production.

S. A. Taylor, of Pittsburg, told of the recent fire at the Monarch mine near Rock Springs, Wyoming, and Mr. Brunton described the walling in and smothering of the fire in the Anaconda mine at Butte. A feature of this struggle was the use of helmets that were supplied with air through rubber hose attached to the pipes that had been used to convey compressed air to the drills, and which was so successful that the miners assured the management that they could, with their use, 'put a wall around hell.' The session closed with some notes on the fire at the Leonard mine, at Butte, by Charles W. Goodale.

On Tuesday, October 25, the party arrived at Havana, and although the departure from New York was an hour behind schedule, aided by fair winds the steamer dropped anchor in the harbor of Havana at 1 o'clock, four hours ahead of time, which afforded a full afternoon for visiting the shops and viewing the city. Wednesday morning was given up to a tour of Cabaña fortress and Morro Castle, and on the return of the party to Havana at noon they were received at the palace by President Gomez, each member and lady being introduced by Mr. Struthers. The president's greeting was most cordial and all of the party were highly pleased. After the reception, carriages which were in waiting conveyed the party to the Plaza hotel for luncheon, after which they were driven about the city, visiting points of interest, and at 4:30 o'clock we were again on board, and precisely at 5 o'clock the journey to Kingston, Jamaica, was begun.

The second session of the Institute was held in the dining saloon of the steamer on Thursday afternoon, October 27, the discussion of mine fires being continued with brief talks by R. V. Norris on the fire in Luke Fidler colliery at Shamokin, Pa.; William Kelly, on four fires at the Vulcan mine at Vulcan, Mich., one of which had been caused by lightning setting fire to the shaft timbers; Edward W. Parker on the recent explosion at Palau No. 4 mine in Mexico; Gardiner F. Williams, on a fire in one of the DeBeers diamond mines in South Africa, where 202 out of 685 men were burned or smothered to death; and Hennen Jennings, on the gold mines of the Rand in which no fire had occurred.

The entire session of Friday was devoted to a talk on the production of pig iron in the electric furnace by Joseph W. Richards of Lehigh University. The subject is one to which Mr. Richards has given a large amount of study. He began with the experiments in electric smelting in France, and the manufacturer of ferro-chrome and other alloys, touched on the study in France made by Dr. E. Haanel on behalf of the Canadian Government and of his experiments in Sault Ste. Marie, and told of his own recent visit to Sweden, where, in company with the Swedish engineers, he made an exhaustive study of the progress in electric smelting of iron in that country. By blackboard illustrations, he showed the development in the construction and shape of the electric furnace, from the cubical box to one shaped like a blast-furnace, hung from heavy girders supported on the walls of the building, and with a beehive coke-oven type of arched chamber below the bosh-plates, with the electrodes placed in the arch of this chamber, and with provision for drawing the gases from the top of the stack and passing them through the bottom of the charge. By thus doing away with the use of any carbon except for combining with the oxygen in the ore, one-third of the quantity of charcoal is used. Mr. Richards is convinced that on account of the decreasing supply and higher cost of charcoal, combined with the labor conditions that obtain in Sweden, the electric furnace is to be the saving factor for the iron industry of that country. As it is now, with a furnace largely experimental in type, and which it was impossible to run to proper capacity, a saving of $1.50 per ton was effected as compared with charcoal iron. A furnace similar to the one described by Mr. Richards has recently been constructed in Shasta county, California.

During the night Jamaica was sighted, and at 6 o'clock on the morning of Saturday, October 29, the ship was docked at Kingston. Here the program as announced was carried out. An early breakfast gave opportunity for some shopping before the start was made at 10 o'clock for the drive to Castleton Garden, and the shops for a couple of hours did a 'land office' business as the men of the party outfitted themselves with duck and crash suits appropriate to the tropics, and the ladies bought linens and lacework. The ride to and from, and the short stop at Castleton Garden, was all that the program and the guide-books claim for it, as was also, on Sunday morning, the ride by special train from Kingston to Bog Walk (a corruption of 'Boca di Agua'), and the carriage ride through the canyon of Rio Cobre to Spanish Town. The return to Kingston was made at noon, and at 2 o'clock the last leg of the outward journey to the Canal Zone was begun.

The fourth session of the meeting was held on Monday afternoon and was devoted to talks on the Canal, the visit to, and the study and inspection of, which was the object of the trip. W. L. Saunders gave a review of the history of its projection from the earliest time, and then discussed the engineering and other technical problems that had been encountered and solved in the work after the construction of the Canal by the United States. One feature specially brought out by Mr. Saunders was the case of the flood-waters of the Chagres river, which is accomplished by the making of the Gatun lake. The Gatun dam, when completed, will impound a lake of water having a total area of 165 square miles, an area considerably larger than Narragansett Bay. The influence of the heaviest torrents of the Chagres river on this spread of water will be relatively insignificant. It is estimated that the utmost effect will be the raising of the level of the lake about twelve inches, and this will be slowly reduced by the overflow at the spillway. The impounding of such a spread of water would not have been possible with a sea-level canal, and the wisdom of the engineers and those in authority in determining on the lock canal is apparent. Moreover, what is not fully appreciated by many persons is that by far the larger part of the Canal is made by the building of the dam, the quantity of excavation necessary to give a deep-water channel in the body of the lake being comparatively small and easily effected.

Mr. Saunders' elucidation of the salient facts connected with the work enabled the party to get a much clearer impression of the undertaking than they could otherwise have done in the necessarily somewhat hurried inspection.

John M. Sherwood, who has visited the Zone frequently during the progress of the work, and has had excellent opportunity to become acquainted with the people, gave an interesting preachment on the social, financial, and political conditions in the Canal Zone and in the Republic of Panama. He dwelt particularly on the common error that the inhabitants are largely illiterate, whereas, among the better classes the young men and women are sent abroad to be educated, and there is to be found in the citizenship of Panama as high a degree of refinement as in any country of the globe. It naturally follows that the somewhat contemptuous behavior of many American visitors to this region and its people is resented and has not served to popularize Americans in Panama.

Some derangement of the machinery that occurred Monday night, the first untoward incident of the trip, caused a delay of three hours, and put the arrival at Colon that much behind time. For this reason the contemplated inspection of the Gatun dam fixed for Tuesday morning was abandoned for the time being, and immediately after disembarking the excursionists were taken by special train to Panama, where ample and excellent accommodations had been provided at the Tivoli hotel, situated on Ancon hill and overlooking the city and the Bay of Panama. No program was arranged for the afternoon or evening.

At 8 o'clock Wednesday morning, November 2, a special train took the party, first through the entire length of the Culebra cut, affording ample opportunity to observe the character of the material being excavated, the work of the drills, and the steam-shovels, and, most interesting of all, the perfect system of handling the trains of empty and loaded cars over a complicated network of tracks, within restricted and continually reducing limits as the channel deepens and narrows, that makes the operations at the Mahoning mine look like child's play. The dirt is certainly flying, and it is flying in a systematic intelligent manner, and on a scale that a few years ago would have been considered impossible. One is struck by the fact that the distribution of effort is so arranged that the entire length of the Canal will be completed practically at the same time. Where the heaviest work is to be done, there the greatest activity is to be observed, but other places are not neglected because the work is light. On the contrary, in the flat areas along the banks of the Chagres river where additional depth must be supplied and where the material is soft, shovels and trains are at work, but in such a way that the results will not have been destroyed by the time the other portions of the Canal are finished.

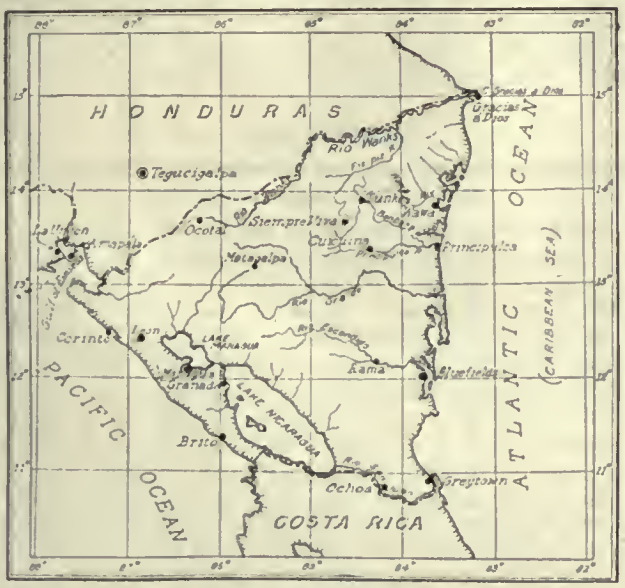
After passing through the cut the special train was hauled over a portion of the re-location for the railroad, whose old right of way will be submerged by the lake, and then returned to Panama over the regular tracks. In the afternoon the Institute party was received by President Pablo Arozamena at his official residence. President Arozamena speaks English fluently, and after the formal presentation, moved among the party in a purely informal social manner and impressed all with his genial, cordial disposition as well as with his dignity and high intelligence.

Thursday, November 3, was the Fourth of July, or Independence Day of the Republic of Panama, and everything and everybody were in fiesta, with which the showers did not interfere. No program had been previously arranged, but a special train was provided in the morning for those who desired to visit the station of Culebra and see the working models of the Pedro Miguel and Miraflores locks. The afternoon was free in order to allow those who desired to witness the festivities of Independence Day in the city. In the evening the entire party were guests of ex-President W. L. Saunders at a Spanish rendition of 'The Merry Widow' at the opera house. The music, which was particularly fine, was thoroughly enjoyed by every American of the party as well as by the native residents of the Isthmian city.

LONDON

Jicaro Gold Estates.—Tin Mines of Nigeria.

It is unusual to see new mining companies floated nowadays, so that the appearance of three during the past week is notable. One of them has been formed to acquire gold mines in Nicaragua, and the other two, tin gravel mines in Nigeria. The company formed to work in Nicaragua is called the Jicaro Gold Estates, Limited. The object is to acquire and develop the San Cristobal and other properties in the Jicaro gold mining district, western Nicaragua. The district is on the Jicaro river, access to which is gained through the port of Corinto on the Pacific side and the town of Leon. The chief vendor is John May, of Leon, and the property has been in charge of E. W. J. Edwards on his behalf. The report on which the property is acquired by the present company has been prepared by Mr. Edwards. The prospectus mentions that James A. Gilmour is consulting engineer to the new company, but no report is made by him. The capital of the company is £75,000, divided into 300,000 shares of 5s. each, of which 109,000 shares and £8500 in cash is purchase price divided



Map of Nicaragua.

between Mr. May and the promoting companies which introduce some subsidiary properties. The promoters have underwritten 60,000 shares at a commission of 10%, payable half in cash and half in shares. The prospectus offers 140,000 shares for subscription by the public. As regards the properties, Mr. Edwards states that the developments at San Cristobal justify a mill and cyanide plant with a capacity of 25 tons per day, and that power can be obtained from a dam on the river Jicaro. He estimates the ore to contain £5 in gold per ton and that the cost should be 16s. per ton. If all the shares are subscribed, £25,375 in cash will be available as working capital.——One of the Nigerian properties referred to above is the Bisichi Tin Co., which has been formed to acquire a tin-gravel property in Bisichi valley, northern Nigeria. H. W. Laws, mining manager for the Niger company, is the consulting engineer and has reported on this property. Trial pits on the company's property have disclosed the presence of 2,120,000 cu. yd. of gravel averaging 7¼ lb. of tin oxide per cubic yard. This means a total content on the proved area of 6800 tons of tin oxide. The river bed is estimated to contain an additional 1000 tons. Mr. Laws estimates the cost at £45 per ton, of which £15 is the actual cost of mining and sluicing. The ground tested is only one-tenth of the whole concession. The nominal capital of the company is £200,000, of which £143,000 in shares and £7000 in cash go as purchase price, and the promoters have subscribed £50,000 as working capital. Among the directors is W. S. Coutts, a partner in Adamson, Gilfillan & Co., of Singapore and Penang.

BUTTE, MONTANA

North Butte-Tuolumne and Butte-Ballaklava-Amalgamated Litgation. —Clarke's Butte Interests.

There seems to be no doubt that a basis of agreement has been reached between representatives of the North Butte and Tuolmune Mining companies, but the nature of it is impossible to ascertain, owing to an evident understanding among those who participated in the conferences leading to the settlement that the terms should remain a secret until after they have been approved by some who are heavy stockholders in both companies.——According to reports the Butte-Ballaklava company is going to make a strenuous fight in the suit brought by the Anaconda Copper Mining Co., which is now set for hearing on December 12. J. A. Percival, secretary of the company, has arrived in Butte to make preparations for the fight and has brought with him Walter Harvey Weed, who is to make an examination of the ground in dispute and will be the principal witness on behalf of the company. Mr. Weed, is now examining the underground workings of the property and also the ground claimed by the Anaconda company. There are those who believe that after Mr. Weed has made his report the Butte-Ballaklava company will be willing to make a settlement with the Anaconda company, and avoid further expense. Mr. Percival, however, is still as pronounced as ever in his denunciation of the Anaconda company and declares the suit will be fought to a finish.——The interests of W. A. Clark have been so lessened in this district the past few months through the sale of his mines and reduction works to the Amalgamated Copper Co. that he no longer requires a general manager in Butte, and A. H. Wethey, who has occupied that position for many years, retires on the first day of the new year. Mr. Wethey has always had a general supervision over the street railway, the bank, the mines, and the reduction works, but now the only active business enterprises operated by Mr. Clark are the bank, the street railway, and one or two small mines. The rumor has been revived that negotiations are proceeding between the Amalgamated and Mr. Clark for the sale of the street railway, together with Columbia Gardens, which is part of the street railway system.——Six of the most prominent copper men in America made an inspection of the Washoe smelter in Anaconda a short time ago. The party consisted of L. D. Ricketts, general manager for the Greene-Cananea company; John Langdon, consulting engineer for the same company; Arthur Cole, superintendent of the smelter at Cananea; Thomas Hoatson, of Calumet, Michigan, and John C. Greenway, general manager for the Calumet & Arizona and the Superior & Pittsburg; and James Wood, superintendent for the Calumet & Arizona. After paying Butte a brief visit they went to Anaconda and spent three days looking over every portion of the big smelter. The party is on a six weeks' tour of the leading smelter cities in the country, and from here they proceeded to Utah, where they were to inspect the plants at Tooele, Bingham, and Garfield. Leaving Utah they were going into Nevada and thence to California. The trip was commenced in Mexico.——Horace V. Winchell is in Butte for the purpose of preparing the case from the expert standpoint on behalf of the Anaconda company against the Butte-Ballaklava company.——The Butte & Superior company is reported to have made $25,000 during October. The result of the bond issue is still unknown, but there is an impression that so far it has not been a success. A short time ago it was stated than an experimental shipment of 1000 tons of ore had been sent to the Clark concentrator and that on the returns received depended a deal of some kind whereby Clark would decide whether he would invest in the bond issue. There is an unofficial statement that the shipment did not come up to expectations; in fact, it is stated that the returns were not nearly as satisfactory as those received from the Basin concentrator. If the experimental shipment had turned out all right it was understood that a portion of the ore was to be treated at the Clark concentrator and Clark was to put money into the treasury of the Butte & Superior company.

DEADWOOD, SOUTH DAKOTA

The Portland M. Co.— The Mogul's Explorations. — Development at Carbonate.—Homestake Hydro-Electric Plant.—Gilt Edge and Wasp.

The purchase by the Portland Mining Co. of the mill and property of the American Eagle company, a deal which was effected at sheriff's sale, gives the Portland a splendid outlet for its ores. For the past few years the Portland has been shipping its ore to the Lundberg, Dorr & Wilson mill. Previous to that time it owned three mills. The first was a stamp-amalgamation plant, erected in 1879, long before any of the modern methods of ore reduction were known. The plant was a failure. Later the company erected a chlorination plant in Deadwood, which was a success, but was destroyed by fire. A cyanide mill at Blacktail was then purchased, and later sold to the Columbus Consolidated. The new mill will be connected with the Portland mines by an aerial tram, something less than one mile in length. The mill has an up-to-date cyanide plant, with a crushing and tank capacity of 300 tons per day. In order to work it up to this capacity, however, it will be necessary to enlarge the slime department. The plant is equipped with a Burt filter, insufficient in capacity. It will be one of several when the mill is fully equipped. The manager, H. S. Vincent, of Deadwood, expects to have the plant in operation by the first of the year. ——The Mogul company has started deep exploration on the Mark Twain, a shaft having been recently begun which will eventually be sunk to quartzite, a distance of probably 400 feet. At a depth of a little over 100 ft., lateral exploration is being conducted in the neighborhood of a porphyry sill. The company's mill, at Pluma, is operating steadily, handling a maximum tonnage.——Developments at Carbonate, by the Black Hills Corporation, R. Bunce, manager, Deadwood, are being watched with great interest. During the summer the company sampled the old dumps of the Seabury-Calkins, Iron Hill, Home Run, and other Carbonate properties upon which it has options, with the result that two cars of ore, netting over $16 per ton, were shipped. Encouraged by the showing on the dumps, two of the old shafts were unwatered. The Seabury-Calkins was found to be filled with débris, or caved, below the 100-ft. point. The Iron Hill has been drained to the 300-ft. level and a station-pump installed which will keep the mine dry to that depth. It seems the old camp is on the eve of an awakening. The company states its intention is to build a 300-ton smelter in the spring. A large percentage of the value is in silver and lead, with a little gold. During the Carbonate boom in '85 and '86, the camp had a smelter, which was run successfully, notwithstanding it was over a hundred miles, at that time, from the nearest railroad. With better railroad facilities and improved smelting methods, it seems to be only a question of ore tonnage to make a payer out of these old properties.——Tunnel No. 2 of the Homestake hydro-electric installation in Spearfish canyon has been completed and a contract let to the Westinghouse company for equipment. Between the diversion dam and the penstock of this system the tunnel work amounts to a total of 23,862 ft. Eight tunnels are included in the total, the shortest being No. 5, with a length of 1284 feet. The longest is No. 2, just completed, with 4152.3 feet. This development will produce 5000 hp. at a distance of 15 miles from the mines and mills of the company. The Westinghouse company has also been awarded the contract for a large portion of the motor equipment for the mills. One order given by the Homestake was for seventy 22-hp. back-geared motors, to be used in operating stamps, one for each ten heads. The Employee's Aid Fund, mention of which has been made in these columns, is operating most successfully, proving to be an important feature in cementing the cordial relations existing between the men and the management.

Engineers representing a group of Eastern capitalists have been busily engaged for a month past in a thorough examination of the Hidden Fortune and Columbus properties. The Hidden Fortune shaft has been unwatered and sampled and the surface showings gone over. The Columbus, too, has been given its share of attention. It is unofficially given out that the results have been encouraging, and that these properties, combined under one management, will become producers.——After a trial run of 30 days, the Gilt Edge-Maid cyanide mill has suspended operations, with a probability that nothing further will be done until spring. It is the intention of the management to erect a concentrating plant, thus saving the free gold and pyrite, and treating the residue by the cyanide process. The run just completed indicates that a considerable proportion of the value is lost when straight cyanidation is attempted, as a portion of the gold is in the free state and some of the balance in the pyrite, which is not easily amenable to the process.——The Wasp No. 2 mill is rapidly nearing completion, and will soon be in operation. Ten months have elapsed since the mill was destroyed by fire, but the new plant will have a capacity nearly a third greater than the old. All foundations are of concrete, machinery throughout is driven by electricity, there are labor-saving devices everywhere, and with its immense low-grade orebody the company is no doubt in better shape than ever before.——Frank B. Hitchings, moving spirit in the Alder Creek, adjoining the Wasp No. 2, is authority for the statement that as soon as the weather is favorable, construction will start on a big mill for that property. The Alder Creek owns an extension of the Wasp orebodies.

NEW YORK

After-Election Comment.—Opinions of Porcupine.—The Various Copper Companies.

The lull following the election has left the Eastern markets without traders, customers, or onlookers. The columns of financial comment put out in New York and Boston are filled with attempted analyses of the situation, though here and there is found franker criticism of the lack of publicity which has turned the public from Wall Street, and an occasional iconoclast who insists that financial leaders, the New York Stock Exchange, and the entire organization covered by the elastic term 'the Street,' have just such amount of public confidence as they deserve and no more. It is hardly to be conceived that a general resumption of business activity can occur, and yet no impetus be given to speculation, but at the same time it is equally certain that the exposures of the methods of high finance are now bearing full fruit in the attitude of the public. Among the houses handling mining shares, one phase most particularly commented on is the fact that, while the market interest, created by the discoveries of gold in Nevada and later the opening of the silver camp in Canada, has been steadily on the wane, for the past two and a half years, the same period has marked an unparalleled progress in the mining industry. A reawakening of public enthusiasm will come with a new generation of market followers, but no enthusiasm can be long sustained nor well deserved until there is instituted a distinct and, when necessary, pitiless policy of publicity. The old saw, "No news is bad news", is well illustrated in the present attitude of promoters and mine managers. When there is a stern "Right about, face!" on this proposition, the mining-share markets will begin to get into stride with the splendid progress of the industry.——The important event of the week locally was the publication of an extended review of Porcupine in the New York *Sun*. The *Sun* is counted the organ of J. P. Morgan and the United States Steel Corporation. Some of the important officials of the latter are said to be interested with Ambrose Monell of the International Nickel Co. in the development of the Dome property at Porcupine. Perhaps this establishes the connection between the *Sun* and the new camp, which is described in more glowing language than is usually seen, save in a prospectus or in boom advertising. The fact remains, however, that Porcupine is evidently receiving the unqualified endorsement of the prominent engineers visiting the new discoveries, and the foundation is being laid for a genuine excitement. William Frecheville, of London; Harry Howard Webb, of the Consolidated Goldfields Com-

pany of Glasgow, Scotland; all commit themselves without reserve as to the showings now apparent and as to a belief in the future of the properties. Whether the magic of a new gold discovery will galvanize the share market into life remains to be seen.——A settlement of the dispute between Tuolumne and North Butte is said to have been made without a sale of the former, or without any exchange of stock between the corporations. While the announcement is said to be made with official sanction, direct confirmation has not as yet been made nor details announced. The buying of Tuolumne has been aggressive.——The Ray Consolidated shareholders met this week in Portland, Maine, and ratified the issue of the $3,000,000, ten-year, 6% gold bonds, and also provided an increase in the capital stock, to permit conversion of the bonds into stock at $20 per share. The bonds are underwritten by Hayden, Stone & Co. The proceeds of the bonds are expected to provide all funds for equipping the property and to carry the company up to the point of initial production.

The Phelps-Dodge company closes its fiscal year with the calendar year. Up to November, the company's production was 117,404,922 lb. of copper. Last year's output was practically 133,000,000 lb. Considering the adverse conditions in the copper metal market, the Phelps-Dodge company has been a remarkable dividend earner, paying 15½% last year, and will undoubtedly show an equal net this year.——A settlement of the Butte-Ballaklava Anaconda litigation was rumored, probably by reason of the compromise of the difficulties between the Tuolumne and the North Butte. Official denial of such agreement is made by wire from the Butte-Ballaklava officials. An examination of the disputed territory and the orebodies claimed by the Anaconda is to be made by Walter Harvey Weed.

The Boston Miami and the Live Oak, in the Globe, Arizona, camp, have made an agreement to do joint churn-drill work along their boundary line.——Development work at the Live Oak property, near Globe, south of the Inspiration and Keystone groups, was begun in December, 1908, and up to July 1, 1910, more than 4000 ft. of underground workings were driven. One drill was placed in operation in the spring of 1910. On July 1 of this year, according to the company's report to stockholders, the ore reserves were estimated at 7,200,000 tons, assaying 2% copper. Development has been carried on during the past summer by means of three drills, and it is stated that the reserves have now been increased to 10,000,000 tons assaying 2% copper.——The Boston Miami was recently taken over by the Arizona Cananea Mines Corporation, which controls a large property at Cananea.——The new bond issue of the American Smelters Securities Co. of $15,000,000 is underwritten by Kuhn, Loeb & Co. The underwriting syndicate was largely oversubscribed. The deal between Kuhn, Loeb & Co. and the Guggenheims was said to have been arranged without consulting the house of J. P. Morgan & Co., a step which was a great surprise to the Street. The bonds are to be offered to the shareholders at par, and are convertible into common stock of the American Smelting & Refining Co. when the bonds sell at par. Proceeds are to be used to liquidate the floating indebtedness of about $11,000,000 of the Securities company and to complete the payment for the Baltimore plant bought in 1907.——The directors of the Calumet & Arizona Copper Co. and the Superior & Pittsburgh Copper Co. are to hold a joint meeting in Duluth next week in an attempt to come together on a plan for consolidation. The smelter of the former company needs additional tonnage, while a merger will save the Superior & Pittsburgh smelter charges, or the necessity of building its own smelter plant.——The troubles of F. Augustus Heinze and the companies which he dominates seem to be perennial. Immediately following the announcement that the Ohio Copper bonds had been successfully placed by the French bankers, comes a sale at auction of 40,000 shares of Ohio Copper at $1.25 per share, 28,128 shares of United Copper common at $4.87 per share, and 18,700 shares of Davis Daly at 82c. per share, the second installment of 50c. being unpaid. It is the understanding in the Street that this is the loan of the Mercantile National to Heinze and that it has been hanging over the market ever since the 1907 panic.——The Bagdad Chase Mining Co., with properties on the Mojave Desert, near Ludlow, California, has been reorganized. The Bagdad Chase is officered and controlled by officials of the New York Central railroad. Among the prominent shareholders are Chauncey M. Depew, of New York, and B. E. Chase, of Rochester. The new organization is the Pacific Mines Corporation, with a capital of $1,000,000. John Hays Hammond is to act as president. The shares of the new company are fully subscribed, and there is to be no participation by the public.——The Rio Plata Mining Co., operating in Chihuahua, Mexico, producing about 85,000 oz. silver monthly, has secured a license in Mexico, and the Mexican subsidiary company, the Compañia Minera Rio Plata, is to go out of existence.

GOLDFIELD, NEVADA

Red Top Extension Development. — Goldfield Annex Lease. — Lower Levels of Goldfield Con.—The Florence.

Production of shipping ore has begun at two separate points in the Goldfield district within the past week and ore of excellent grade is being sent to the samplers, while there is good promise that the shipments will be continued. The more important developments appear to have been made on the Red Top Extension, a small fractional claim situated between the Clermont and Miss Jessie claims of the Consolidated Mines Co., and between the end-lines of these claims. Apparently the new find is in a part of the Clermont or Red Top veins. The ore was exposed in a raise, 60 ft. above the 500-ft. level, and 100 ft. southwest of the shaft which had been sunk by lessees to a depth of over 600 ft. The lessees worked this ground about two years ago, but found no ore of commercial grade, and the work was stopped. It was resumed, however, under a lease that was partly financed by some of the owners of the ground. The lessees say they have exposed in the raise an ore-shoot 3½ ft. wide, the ore in which averages $40 per ton. The other new producer is the Goldfield Annex lease, on the Polverde claim of the Jumbo Extension, the shaft of which is close to the Clermont. This lease produced some ore last year, but the ore-shoot which was lost on the 800-ft. level was later recovered. Ore shipments are now being sent to the sampler. The Grizzly Bear workings at a depth of 1170 ft. are on a vein of low-grade ore. This lease has a two-compartment shaft 1200 ft. deep, the deepest in the district, and has done considerable development. ——According to reliable information, a constant improvement is apparent on lower levels of the Consolidated mines. The orebody exposed a short time ago on the 1000-ft. level of the Clermont has maintained its high average value and volume and contains ore of the grade that the company has been shipping to smelters. The October shipments of smelting ore averaged $840 per ton; and the average of all ore taken from new work on the 1000-ft. level was 3.28 oz. per ton. The stopes on the 750-ft. level of the Clermont continue to yield rich ore, and there still remains a large tonnage of similar ore in the Mohawk mine.——The results of new work on the Combination have been gratifying and it is believed the orebody exposed lies parallel to the vein developed in the Hampton stope. Seams of high-grade ore, in which free gold is visible, have been mined on the fourth and fifth levels almost to the boundary line of the Florence. It is said that the ground for a width of from 100 to 150 ft., between the Combination shaft and the old January workings, has ore that can be profitably treated. New development has progressed at the usual rate during the fiscal year ended with October.——The Florence Goldfield company maintains a daily production and mill treatment of 150 tons. Shaft sinking continues and a station will soon be cut at 600 ft. depth. The purpose is to sink to 1000 ft. Exploration work from the 600-ft. station is to be carried out. The Florence is said to be making a satisfactory profit from the treatment of comparatively low-grade ore. Combination Fraction is treating 50 tons per day at its leased 20-stamp mill.

General Mining News

ALASKA

(Special Correspondence.)—On Prince of Wales Island another 1400-ton shipment of sulphide ore from the It mine is being transported by barge to the Tyee smelter. A diamond-drill is being used with good success in prospecting the ground ahead of main workings.——The Dean prospect, about a half mile west of the It, is being developed by the Pacific Metals Co.; 3000 tons of ore that will net $10 per ton is now reported in sight. The third payment has been made to the original owners of this property.

Ketchikan, November 20.

Georgetown, situated on the Kuskokwim river, 350 miles upstream from Bethel, is now recognized as the principal trading point in that district. Provisions are reported plentiful for the winter in Kuskokwim camps. Julien creek, a short stream that flows into Yukwonilnuk river, is reported as having good pay-gravel. The latter is a tributary of the Kuskokwim. The great flats of the Yukwonilnuk contain some gold at bedrock.

The report of the Alaska United Gold M. Co. for the month ended October 15, 1910, is as follows: Ready Bullion mill, 120 stamps, ran 28 days, 18 hr., 12 min.; water power, 26 days, 1 hr., 57 min.; steam power, 2 days, 16 hr., 15 min. Ore crushed, 18,890 tons; concentrate saved, 321 tons. Estimated gross value of free gold, $24,139.67; base bullion, $1577.89; estimated gross value of concentrate, $15,807.98; total, $41,525.54. Realizable value, $39,357.15. Operating expenses, $27,868.75; net operating profit, $11,488.38; construction expense, $4551.67. Yield per ton of ore milled, $2.198.

The 700 Claim mill, 100 stamps, ran 29 days, 16 hr., 43½ min.; water power, 18 days, 13 hr., 55½ min.; steam power, 11 days, 2 hr., 48 min. Ore crushed, 16,197 tons; concentrate saved, 327 tons; estimated gross value of free gold, $21,215.54; concentrate, $17,499.16; total, $38,712.70. Realizable value, $36,536.35. Operating expenses, $24,297.89; net operating profit, $12,238.46; construction expense, $2749.63; yield per ton of ore milled, $2.39. Development work on Ready Bullion, in ore, 318 ft.; assay value, $1.06 to $2.46; development on 700 Claim, 146 ft in ore, assays $4.78 to $4.94. Stock of ore broken: Ready Bullion, 678 tons; 700 Claim, 14,767 tons.

The report of the Alaska Mexican Gold Mining Co. for the month ended October 15 is as follows: Mill time, 30 days. The 120-stamp mill ran 29 days, 15 hr., 57 min. Water power, 13 days, 14 hr., 33 min.; steam power, 16 days, 1 hr., 24 min. Ore crushed, 18,516 tons. Concentrate saved, 350 tons. Estimated gross value free gold, $33,643.13; base bullion, $474.01; estimated gross value of concentrate, $32,711.78. Total, $66,828.92. Less amount due Alaska United Co., $1765.76; net, $65,063.16. Total realizable value, $62,746.80. Operating expense, $27,472.80; net operating profit, $35,273.93. Construction expense, $7103.02. Yield per ton of ore milled, $3.51. Stock of broken ore, 7821 tons. Development, 216 ft. in ore, 233 ft. in waste. Assay value, $2.98 to $4.58.

The report of the Alaska Treadwell Gold Mining Co. for the month ended October 15 is as follows: Mill time, 30 days. The 240-stamp mill ran 29 days, 5 hr., 38 min. Water power, 26 days, 4 hr., 42 min; steam power, 3 days, 56 min. Ore crushed, 33,740 tons; concentrate saved, 580 tons. The 300-stamp mill, water power, ran 29 days, 14 hr., 50 min. Ore crushed, 49,224 tons; concentrate saved, 860 tons. Total concentrate, 1440 tons. Estimated gross value of free gold, $104,940.51; base bullion, $1570.12; estimated gross value of concentrate, $73,650.75. Total, $180,161.38; total realizable value, $170,471.98. Operating expenses, $93,443.60; net operating profit, $77,028.38. Construction expense, $18,827.84. Yield per ton of ore milled, $2.17; stock of broken ore, 6904 tons. Development, 247 ft. in ore, 287 ft. in waste; assay value, $3.23 to $18.07.

ARIZONA

GILA COUNTY

(Special Correspondence.)—Nearly all the machinery is in place at the concentrating plant of the Miami Copper Co. Production at the rate of 1000 tons a day will be commenced January 1, 1911. The total amount of underground work is 76,069 ft., including the several shafts. Last week 302 ft. of driving and raising were done on and above the 370 and 420-ft. levels. The power plant and concentrate bins are practically complete. The latter have a capacity of 1500 tons. The company is employing about 600 men. B. Britton Gottsberger is general manager.——T. W. Hamilton, manager for the Summit Mining Co., is visiting the property, situated 10 miles west of Miami. He is much pleased with the results of developments since the purchase of the property a few months ago. In the course of developing much ore of high copper content has been discovered. Apparently, there is enough ore in sight today to return to the owners the full amount paid for the property. Some of the ore exposed runs from 28 to 31% copper.——It is probable that during the stay of T. W. Hamilton some definite policy concerning future work at the Cactus mine will be outlined.——The Arizona Commercial Copper Co. is sinking its seventh diamond-drill hole at a location west of the Eureka shaft. The first six holes, two of which found ore averaging between 5 and 6% copper at a depth of 900 ft., were east of the Eureka shaft. The pumps are raising approximately 1600 gallons of water per minute.——The drift on the eighth level of the Superior & Boston mine gives promise of finding a body of oxidized ore when the Great Eastern vein is struck. The foot-wall rock is copper stained.——The Arizona-Colorado Copper Co. has two machine-drills working in a stope on the eighth level where the average copper content is about 4%. John F. Shaw is manager.

YAVAPAI COUNTY

The Jerome Verde Co., the Haynes Copper Co., and Arkansas & Arizona are carrying on development work on their respective properties in the Black Hills district, east of Jerome. The first named is sinking a shaft and pumping water, the second is driving on a 6-ft. gold-bearing vein, while the last is at present sinking below the 600-ft. station.

YUMA COUNTY

Ore is being shipped by the Wardwell-Osborne Copper Mines Co. to the smelting plant at Humboldt. It is reported that the first carload shipped netted $500. Three more cars are to be shipped this month. Development expenses are being paid out of the proceeds of ore sold. Parker is the shipping point.——John Sanborn, who has partly developed a mine in Riverside mountain, is preparing to ship 1000 tons of ore to the Humboldt smelter. This ore is on the dump; the mine is 8 miles from Calzona station. The freight rate to Humboldt is $2.50 per ton on ore running from $15 to $25.——The mill of the Desert Mines Co., in the vicinity of Vicksburg, was to begin operating November 15. B. J. Hall, identified with the company, states that mining and milling costs will be about $4.50 per ton of ore.——A rich vein of free-gold ore is said to have been discovered on the property of the Golden State M. Co. at Whipple Wash, near Parker. Some of the ore was sacked and shipped.

CALIFORNIA

CALAVERAS COUNTY

The Calaveras Copper Co., whose large holdings are at Copperopolis, has extensive development from a number of shafts, the deepest of which is 800 ft. These shafts are aligned along the strike of the principal vein, the ore from which carries chalcopyrite that is said to sample 4% copper. It contains neither gold nor silver. The property has much new equipment, including an oil-burning reverberatory smelting furnace, a 125-ton blast-furnace, McDougall roasters, two stands of converters, and a concentrating plant. All machinery is to be electrically operated. A large tonnage of ore is broken in the stopes, and there

is said to be 150,000 tons on the surface. J. H. Trerise is manager, with Nicholas Treloar in charge of the mine work.

KERN COUNTY

The oil production of California for October, 1910, was as follows: Kern River, 1,064,000 bbl.; Coalinga, 1,488,500; Midway, 939,466; Sunset, 521,560; McKittrick, 379,300; Salt Lake-Sherman, 275,500; Los Angeles City, 36,500; Whittier-Coyote, 93,200; Fullerton-Brea Canyon, 460,500; Ventura, 44,700; Newhall, 10,350; Santa Maria, 725,000; Summerland, 4500. Total, 6,046,076 bbl., a decrease of 687,459 bbl. from the production of the previous month. The October consumption was about 5,200,000 barrels.

C. J. Teagle, of Johannesburg, has given a bond for the sale of his placer property situated at Summit. H. E. Cunningham has sampled the deposits for those taking the bond. The property was worked profitably in early days, and is said to contain a good yardage of unworked gravel that will pay to handle. A plant is to be installed for this purpose. It is close to Teagle station on the Southern Pacific.

NEVADA COUNTY

(Special Correspondence.)—The North Star Mines Co. has commenced the building of a road-bed for an electric car line from the Central shaft to the Massachusetts Hill mine. A suspension aerial railway is employed to carry out the work. Four cables are strung across a ravine, ties are fastened to the cables, and rails spiked to the ties. The ravine is filled by means of cars of broken waste quartz, which discharge from the suspended railway. It is reported that developments at the Massachusetts Hill will commence early next year. The company is pushing development vigorously at the Cincinnati Flat group with pleasing results. A pipe-line is being laid to the property from the North Star compressor house, and a water main is also under construction. At the Central shaft a new hoist is being installed.——Developments at the Empire progress steadily with the 40-stamp mill running. The new cyanide annex is nearing completion. All the tanks are in position and the machinery is being installed. The approximate cost is $50,000.——The ore-shoot recently opened in the Cassidy Con. continues to show high-grade milling quartz.——The Pennsylvania is temporarily idle because of lack of water, but is expected to resume soon. The W. Y. O. D., owned by the Pennsylvania company, is working steadily; Bennet Opie is superintendent.——The Golden Gate Co. is installing a 55-hp. electric hoist, and contemplates sinking the shaft to a depth of 1000 ft. Mr. Martin, the superintendent, reports an 8-ft. vein at the bottom of the 600-ft. shaft. San Francisco people are interested.——It is expected that the unwatering of the Prudential mine will be accomplished before the end of the week.——Fire caused damage of $8000 to $10,000 at the hoist of the Pittsburg mine last Friday. The structure was destroyed, but the plant was not seriously injured.——A shoot of bonanza ore has been opened in the lower adit of the Red Ledge mine, near Washington. Its extent is as yet undetermined.——The Grover-Murphy mine has been purchased by the Honolulu M. Co. for $20,000. Harry B. Gray is superintendent.

Grass Valley, November 21.

SAN BERNARDINO COUNTY

The Bagdad-Chase mine, and the adjoining Roosevelt group, situated seven miles from Ludlow, have been sold to the Pacific Mines Corporation of New York; the deal was arranged by Frank A. Keith of Los Angeles.

SIERRA COUNTY

The Red Star mine, at Alleghany, has a body of rich ore which is believed to be the northern extension of the Tightner lode. The find was made by driving a cross-cut from the Eureka to the Red Star. It is said the entire face of the cross-cut is in ore of good grade. L. P. Woodbury is manager.

TUOLUMNE COUNTY

(Special Correspondence.)—Ore of extraordinary richness has been uncovered in the Italian Camp mine, which adjoins the Belvue on the north. The quartz is thickly speckled with gold, one piece weighing 200 lb. being valued at more than $2000. It is the belief that the orebody is one of the best ever discovered in that district. The property was bonded to an Eastern company only a few weeks ago, and until then was worked by the owners, McCormick, Rolleri & Froli, who installed a 4-stamp mill just prior to the change. Development is progressing steadily.——The Climax mine, recently bonded to E. Sergerstrom and others, is showing excellent prospects, much of the ore now being extracted in development being of high grade.——It is reported that the shaft at the Yorktown mine will be sunk to 500 ft.; also that cross-cutting and much driving will be done.——It is said development work is to be resumed at the Toledo mine, northwest of the Rawhide, and owned by R. P. Clement, of San Francisco. As nothing has been done for six years the shaft, 580 ft. deep, must first be retimbered.

Tuolumne, November 21.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A body of mixed ore and quartz, exposed in the heading of the Homestake adit on Lincoln mountain, is 27 ft. wide. Samples taken across the streak assayed 0.83 oz. gold per ton.——The deal for the transfer of the Santiago mine in East Argentine probably will be closed in a few days. The consideration is to be $500,000, with a cash payment of $100,000. The North American S. & M. Co., the purchaser, will commence development.——The Vidler adit, which is being driven under the Continental Divide, is advancing at the rate of 7 ft. per day. In another vein recently encountered, a streak of galena was opened that is from 6 to 8 ft. wide. Tests show 90 oz. silver to the ton and 45% in lead.——Two feet of ore has been encountered in the raise from the 240-ft. level of the Astor mine on Democrat mountain, assays of which showed 80 to 2000 oz. silver to the ton. This is considered the best discovery that has been made in upper Clear Creek district in the last six years.——The East Griffith mine, on Griffith mountain, is to be operated by lessees. J. N. Stewart and associates have taken a block of ground 300 by 300 ft. and have started stoping on an 8 to 12-in. streak of ore that assays 117 oz. silver and 0.50 oz. gold to the ton. The Griffith M. Co. contemplates sinking the shaft to a depth of 700 ft.——White & Co., lessees on the Gold Dirt, have commenced shipping smelting ore, the average of which is $55 per ton.——Louis Rebo, leasing on the Revenue mine up Geneva gulch, is shipping ore that mills 500 oz. silver to the ton.——Work on the Paragon adit has been resumed. The plan is to extend it so as to intersect the Ruler vein 160 ft. ahead.

Georgetown, November 19.

GILPIN COUNTY

(Special Correspondence.)—The Topeka mine in Russell gulch has become one of the heaviest shippers of the county. A force of men is now employed on the twelfth and thirteenth levels, and shipments of smelting ore are being made.——P. Sweeney, owning a group of claims up Fall river, has uncovered a foot of ore that will mill 2 oz. gold to the ton. The streak has been opened a length of 30 ft.——John Bosper, leasing on the seventh level of the Topeka mine, has an 18-in. streak of pyrite that mills 3.50 oz. gold to the ton. Lewis & Myers, at work on the same level, are stoping a body of mill ore 3 ft. wide that runs $14 to the ton in gold.——Shipments will be started soon from the Golden Slipper property on North Boulder creek. A streak of ore 22 in. wide has been opened that assays from $16 to $20 to the ton in gold.——A force of 80 men is employed on the Addueldel mine and shipments of concentrating and smelting ore are being made regularly.

Central City, November 19.

The ninth level of the Freedom mine, on Winnebago hill, is being put in order so that an examination may be made.

Sinking is to be resumed as soon as the sump is pumped out.——Lessees on the Baker mine, on Quartz hill, are mining on the 200-ft. level, taking ore from a shoot 150 ft. long, having 200 ft. of stoping ground. The vein is 4 ft. wide; the ore mills $40 gold per ton by amalgamation. Selected smelting ore in small lots runs $120 per ton.——The Gilpin-Eureka M. Co. has opened a 12-ft. vein of ore running $10 per ton on its 600-ft. level. The same vein on the 500-ft. level was 4 ft. wide, and this included a small streak of smelting ore which sampled $60 per ton.

LAKE COUNTY

The property of the Clear Grit M. Co., at Leadville, is being developed under direction of C. J. Moore. The shaft was sunk 185 ft. and at this depth a station was cut and a pump installed. Driving from this station in the porphyry is in progress, the plan being to open an ore-shoot on its rise.——Ed. Brady and Thomas Flannery, having a lease on the Dunkin on Fryer hill, have made small shipments of ore at regular intervals in the last six months. Recent development resulted in opening a streak of ore running high in silver with lead carbonate.——It is reported that a 60-ft. vein carrying lead sulphide, accompanied by argentite, was discovered in the course of development from the Yak tunnel.——Kirke White and Howard E. Burton of Leadville have taken a lease on the Reindeer, on Rock hill, and expect to install some new equipment. Zinc carbonate found on the dump assayed 37% zinc. The body of ore which they hope to reach was opened by the Stevens shaft on an adjoining property.——The Hayden shaft, on Fryer hill, is producing 60 tons per day of zinc carbonate.

SUMMIT COUNTY

The Hamilton mine, near Breckenridge, is active again after an idleness of several years. Charles Andrew and Bert Acton have taken the contract to drive two cross-cuts for the purpose of opening two veins.

TELLER COUNTY

The Roosevelt drainage tunnel in Cripple Creek district has been completed, the cost having been approximately $600,000. It drains the mines of the district to a depth of 730 ft. below natural water-level. T. R. Countryman, engineer in charge of the work, estimated the volume of water in the basin to be drained at 50,000,000 gal. per vertical foot, with the constant addition of 1000 gal. per minute. The unwatering of this basin, according to an estimate, will make available a tonnage of ore valued at $192,500,000. The lowering of the general water-level, as the result of the drainage, is stated to be at the rate of 10 ft. per month. The length of the tunnel is about three miles; the rock passed through was mostly granite, and, except at the portal, no timbering was required. Most of the work was performed under contract by A. E. Carlton. The funds required to meet the expenses of the work were subscribed by 20 mining companies whose properties are to be drained by the tunnel.

IDAHO

IDAHO COUNTY

The American Eagle mill at Elk City turned out gold bullion worth $4200, and 10 tons of concentrate worth $900, as the result of 15 days' run. The ore from which these products came was taken from a shoot opened on the third level of the American Eagle mine. The property is being operated by A. W. Boyd as lessee.

SHOSHONE COUNTY

A carload of tungsten ore was recently shipped from the Golden Winnie mine at Murray. This is an old mine which has also produced gold ore. It has a small mill in operation.

MICHIGAN

The ores from the Osceola mine, near Houghton, yielded an average of 17.1 lb. of copper per ton for 1908; 16.9 lb. for 1909, and for 1910 it is announced that the average recovery may be still lower. For the first ten months of this year, the mine produced 15,981,430 lb. of copper, as against 21,535,238 lb. for the first ten months of 1909. The cost of production for 1909 was 9.47 cents per lb., and a slight advance in cost is anticipated for 1910.

MONTANA

LINCOLN COUNTY

The Snowshoe mine, one of the principal properties in Libby district, has had its pumps in operation the past month and a small force of men has been employed. These facts indicate that the mine, which has been inactive for four years, is to resume operations. It is a silver-lead property and is opened by a 400-ft. shaft. Production in former years was profitable, the mineral having been marketed in the form of concentrate. The Snowshoe is situated twenty miles from Libby, but it can now be served by the Dawson Lumber Co.'s railroad, which extends almost to the mine.——The Shaugnnessy Hill mine shipped a car of silver-lead ore to East Helena, and has two more cars ready for shipment. A railroad spur may be built to the mine. The operators are A. J. McCorkle and T. H. Town.

NEVADA

LINCOLN COUNTY

The Nevada-Utah Mines & Smelters Co., with Ernest R. Wooley as manager, and H. C. Parker as superintendent, has acquired the Raymond & Ely and other mines in Pioche district, and has commenced work. The Raymond & Ely No. 5 shaft is to be put in order and mining operations are to begin at the Day mine. It is predicted that this organization may acquire other important mines of the district.

NYE COUNTY

(Special Correspondence.)—Sinking the Belmont shaft from the 1100-ft. level is progressing, while development on the various levels is under way. The Belmont vein is being followed on its dip from the 1166-ft. level. As soon as the new surface plant has been completed the company will prospect other veins on its property.——No. 2 shaft of the West End is 80 ft. below the 400-ft. level, and as soon as the 500-ft. point is reached a station will be cut and a new level opened. The main workings are centred by way of the 275 and 400-ft. levels, where large bodies of ore have been proved. All ore shipments are made from these levels. On the south side of the property, along the MacNamara line, a 4-ft. vein of fair-grade ore has been opened.——The Montana mill is crushing approximately 1052 tons of ore per week, maintaining an extraction of 92.6%. Stoping on the Triangle and Martha vein systems is in progress.——Developments on the 800-ft. level of MacNamara are in progress, several raises being made on the foot-wall of the thick quartz lode in order to cross-cut the vein at those points. Ore shipments amount to about 200 tons per week. ——Thirty stamps are dropping at the Tonopah Extension, crushing 135 tons per day, the extraction being 92%. It is stated that profits average about $15,000 per month.——The Manhattan Mining & Leasing Co. is sinking in shaft 14 on Union No. 9 claim. New machinery has been installed and four shifts are employed.——The 5-stamp mill at the Buffalo is nearly completed.——The War Eagle mill is running steadily on ore from the Dexter group. About 40 tons is treated daily.

Tonopah, November 19.

The 10-stamp mill of the Nevada Reduction Co., at Manhattan, is operating on ore from the Swander lease. The crushed ore passes over plates, then to a Dorr classifier, the sand from the latter being pulverized in a tube-mill; the slime from the Dorr machine joins the tube-mill slime, and this stuff passes over secondary plates, thence to Pachuca agitating-tanks for cyanidation, and finally to Oliver filters. Precipitation in zinc-boxes follows. C. L. Logue is in charge of the mill.——The Rawhide Coalition and Rawhide Queen mines, in Rawhide camp, have produced $385,000, according to mill and sampler returns. The Queen owns a mill which treats ore from both mines. It is claimed both properties are out of debt and have funds in their treasuries.

ORMSBY COUNTY

The Athens, the only patented claim in the county of Ormsby, is being worked under lease after having been idle since 1874. A stringer of high-grade ore was recently encountered, and some ore has been sacked for shipment. ——The Eagle Valley M. & M. Co., with offices at McGill, has four claims adjoining the Athens on which development has been in progress for the past six months. An adit has been driven 300 ft. and a 60-ft. winze sunk. While enlarging a station for the installation of a hoist, a 6-ft. face of gold-bearing quartz was encountered which pans freely. A cross-cut is being run from the winze to cut the vein.

McGill, November 21.

STOREY COUNTY

The milling plant of the Charles Butters Co., in Six-Mile canyon, Virginia City district, is to be closed down for the winter. On this account ore shipments from the Mexican, Chollar, and Potosi have been discontinued. Ore to be counted on was not deemed sufficient to keep the plant in operation steadily through the winter. During the closed-down period the mill is to be put in first-class condition, with the plan of resuming operations next spring.

Butters Cyanide Plant, Six Mile Canyon.

WHITE PINE COUNTY

The Nevada Lead Metals Exploration Co. has leased its San Toy group at Hamilton. This was formely known as the Silver Plate mine, which produced well in early days. Hamilton camp has a large tonnage of silver-lead ore that could be profitably shipped if it had a railroad connecting with outside points.

It is announced at Ely that the Giroux Con. Mines Co. has definitely decided to erect a smelting plant for the treatment of its ore. The mine is at Kimberly, seven miles from Ely.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The mill of the Ernestine Mining Co. crushed 643 tons of ore in 7 days, from which was produced 46 sacks of high-grade concentrate. Precipitate smelted yielded 6123.60 troy ounces of gold and silver bullion. Headings were advanced 96 ft. during the week, the eleventh level west continuing in rich ore.——Officials of the Socorro mines visited the property on the 13th. Development in the lowest levels continues in high-grade milling ore.——At the Deadwood mine a pipe-line is being laid and cross-cuts are being driven both ways from the 500-ft. station in the shaft. The new vein recently discovered on the foot-wall side is to be opened, and the Last Chance and Queen lodes are to be opened on the hanging-wall side.——The Perseverance shaft of the Enterprise Mining Co. has been re-timbered and the mine will be sampled in the lower workings.——The mill of the Treasure Mining & Reduction Co. began operating on the 7th. The hydro-electric power plant is reported working satisfactorily.——Miners' quarters and other buildings are being constructed at the Gold Dust mines.——A vein of good ore is being developed on the 200-ft. level of the Trilby.

Mogollon, November 19.

OREGON

BAKER COUNTY

The Eastern Oregon Mining Congress, which met at Sumpter, October 20 and 21, was well attended by mining men of that part of the State. Papers were read and matters of interest were discussed.——The Mormon Boy mine, at Cable Cove, has been taken over by S. C. Love; work has been resumed with Richard Addoms in charge. In the 4-ft. vein there is said to be one to two feet of profitable sulphide ore.——The Highland mine, situated close to the North Pole mine, in Cracker Creek district, shipped 555 tons of ore since September 1, which sampled $44.50 per ton, the net returns amounting to $17,247.50.

GRANT COUNTY

The mine and mill of the Cougar M. & M. Co. have been sold to E. D. Sanders, of Spokane, and his Eastern associates. The property is situated in the Blue mountains, four miles west of Granite. The mine is well developed, and a considerable tonnage of mill ore is said to be accessible. It is announced that the mill capacity is to be increased.——The Dixie Meadows mine, near Prairie City, has been sold to the Dixie Meadows M. Co., made up largely of Eastern people; the price was $75,000, paid in cash. The plans contemplate further development this winter and the building of a new mill later. L. A. Greenley is to be in charge.

JOSEPHINE COUNTY

In Galice district the Golden Wedge mine is to resume operation as soon as water for power is provided.——Hydraulic work is to begin on the Old Channel mine with the commencement of the rainy season.——The dredge on the Jewell & Lewis property is ready to begin work.——The mining people of Galice are making a determined effort to have the National Forest boundaries so changed as to place that mining district outside of the timber reserve.

SOUTH DAKOTA

According to the report of the State Mine Inspector, recently filed at Pierre, the gold production of the Black Hills for the past year was $4,921,304, which is a decrease of $1,500,000 from what has been considered the normal production. The cause of the decrease is ascribed chiefly to labor troubles at the Homestake mine.

LAWRENCE COUNTY

The first dredge built in the Black Hills is being constructed at Mystic, a short distance below famous old Castleton, in a neighborhood that has produced placer gold for more than thirty years. The plant will be operated by electricity, generated in a station close to the Burlington tracks, where steam coal will be delivered at a reasonable figure. The dredge will have a capacity of 1000 yards a day, and will be running within three months, if the winter is not too severe.——In the death of Moses E. Thompson the West lost one of its well-known men. Mr. Thompson had operated in nearly every important Western camp at some time during more than fifty years of experience. His biggest strike was in the Lady Franklin, in New Mexico, 25 years ago. He had mined in California, Montana, Nevada, on the Comstock, and in other Western States, coming to the Black Hills 12 years ago. He was a successful man.

UTAH

BEAVER COUNTY

The Horn Silver M. Co., whose mine is at Frisco, has decided to construct a new concentrating mill of 75 tons daily capacity, for treating its complex ore, which contains zinc, lead, silver, and gold. It is stated that the mine contains a big tonnage of ore broken and available. The tailing dump contains about 100,000 tons of material, estimated to run 6% lead, 6% zinc, and 4 oz. silver per ton. M. C. Morris, of Salt Lake, is the company's manager.

BOX ELDER COUNTY

The Salt Lake Copper Co., whose mine is close to the western border of this county, is shipping 150 tons of iron ore daily to the Murray smelter. The ore carries 56% Fe, 3% being deducted for silica. The mine, which is in the Pilot Peak range, has an aerial tramway over which the ore is transported to bins at the base of the mountain. A 4-mile railroad spur extends from Tecoma station to the shipping bins.

JUAB COUNTY

The Opohongo, in Tintic district, has been well developed and is in position to ship ore regularly. Orders have been given to build a spur to the mine from the main line of railroad. The principal development is on the 500-ft. level, though it is claimed ore has been opened on the 900-ft. level. It is stated that the expense of development has been paid from proceeds of ore sold. The mine is in the neighborhood of the Black Jack, Ajax, and Gold Chain, and is managed by William Hatfield. The ore carries gold and copper.——The Chief Consolidated, situated close to the town of Eureka, has a new body of ore sampling 100 oz. silver per ton; it was struck by driving southward on the 1400-ft. level, and is one of a series of parallel ore-bodies which have been intersected. At the sub-level, 28 ft. below the 1400-ft. level, and 300 ft. south of the main cross-cut, a well-defined ore-shoot has been opened, and the miners are driving for the same shoot on the 1500-ft. level. In 19 months the Chief production was sufficient to pay all operating expenses and make a net earning of $28,000. The October earnings are given at $25,000. Walter Fitch, the manager, states that the advance in the price of silver has greatly benefited the Tintic district mines.

SALT LAKE COUNTY

The mill of the Utah-Apex company is undergoing repairing and overhauling. Recently a find of silver, lead, and copper ore was made in driving the Parvenu adit on this property; also, a new body of silver-lead ore was opened in driving on the south branch of this adit. It is said a body of copper ore was encountered in making a raise from No. 7 level. During the next four months no milling ore, but shipping ore only, is to be mined. This will permit the use of the principal drilling force on development work.

SUMMIT COUNTY

The Columbus Con. M. Co., operating at Alta, has levied assessment No. 4 of 10 cents per share, for the purpose of meeting certain obligations and to continue development work. Tony Jacobson, the manager, states that the ore now exposed is too low in grade to enable the company to pay operating expenses.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The Le Roi mine resumed shipments the past week, sending a small tonnage to Trail smelter. The future operations of this mine cannot well be determined at this moment, though it is stated the property is likely to be taken over by a company with plenty of capital.——The shipments of ore and concentrate from Rossland district for the week ended November 12 were 4526 tons; and for the year ended that date, 203,457 tons.

Rossland, November 19.

(Special Correspondence.)—The coal mine of the Boundary Mining & Exploration Co., near Midway, shipped its first car of coal the past week. Work is being continued on the two seams. Buildings are being erected on the property recently acquired on Myers creek, nine miles from Midway, by a local syndicate. A government analysis of the coal of this locality showed 69% fixed carbon and 8% ash.——The Greenwood smelter of the British Columbia Copper Co. is producing copper at the rate of a million pounds per month, and gold and silver valued at $75,000. ——The Nickel Plate mine of the Hedley Gold Mining Co. is producing 4500 tons of ore per month, of an average value of $12.18. The treatment of this ore in the company's 40-stamp mill results in an average recovery of $11.25, mining and milling costs being $5.47, leaving an average net profit of $5.78 per ton. For the year ended August 31, 1910, the earnings were $284,403, and $143,520 was paid in dividends.——The shipments of ore from Boundary district for the week ended November 12, 1910, were 33,145 tons, of which 19,370 tons was from the Granby mines. District shipments for the year ended this date were 1,443,401 tons.

Greenwood, November 19.

(Special Correspondence.)—A 6-drill Rand air-compressor and drilling plant have been purchased for the Lucky Jim zinc mines at Three Forks. Development work will be carried on all winter, and the mine is expected to be ready for shipping ore in the spring. Occasional shipments of silver-lead-zinc ore may be made during the winter over snow roads to Three Forks.——Development will be pushed on the Pingree mine this winter.——The Granite-Poorman near Nelson is to be operated on a larger scale. The property is now in control of Thomas Gough and associates. It is estimated the ore in the stopes will yield a net profit of over $155,000. During the past year about 10,500 tons of ore has been put through the mill, the net profits from which were close to $26,000.——The ore and concentrate shipments from the Slocan-Kootenay district for the week ended November 12 were 6609 tons.

Nelson, November 19.

ONTARIO

(Special Correspondence.)—B. E. Cartwright, president of the Temiskaming Mines of Cobalt, has organized the Pearl Lake Gold Mines, Ltd., to take over the four Cartwright properties at Pearl Lake, in the Porcupine district. Preliminary work on these properties is said to have opened between 50 and 60 veins, 12 of which show free gold on the surface.——In the southwest corner of claim No. 13,710 several veins have been uncovered which are believed to be an extension of the vein system on the Timmins properties. Some of these veins show free gold.

Cobalt, November 19.

(Special Correspondence.)—John P. Heffernan, of Montreal, one of the largest owners of the Crown Chartered company and vice-president of that company at Porcupine, has assumed active control of development. A large force will be employed.

Porcupine, November 10.

MEXICO

CHIHUAHUA

La Republica operations, out from Ocampo, for October resulted as follows: Ore milled, 1163 tons; gross returns, ₱73,655.63; operating costs, ₱46,457.13; construction costs, ₱1,484.57; surplus, ₱25,711.93.——The Rio Plata Mining Co., with offices in New York, has been chartered under Mexican laws; its subsidiary, the Compañia Minera Rio Plata, will go out of existence. The mine is in Chihuhua, 85 miles from the Kansas City, Mexico & Oriental railway. The output, amounting to 85,000 oz. of silver per month, is carried by mule to Sanchez station; quarterly dividends are paid at the rate of 8% per year.

SONORA

It is announced that the Greene-Cananea Copper Co. will smelt the concentrate produced at the mill of the Miami Copper Co. at Globe, Arizona. Bins of 500-ton capacity are being built at the smelter for receiving this product. A mechanical drier is also being installed.

Company Reports

CAMP BIRD LIMITED.

The Camp Bird Limited has issued its annual report for the year ended April 30, 1910. It shows that after treating 79,914 tons of ore, there remained 45,300 tons of ore broken in the stopes, with 38,600 tons estimated as blocked out, making a total of 83,900 tons of ore in reserve. From the ore treated during the year an extraction of 95.5% was obtained, yielding $33.18 per ton in gold. The cost, exclusive of depreciation, was $6.93 per ton, with the addition of 47 cents for taxes and $1.55 for development. The bullion shipped during the year was valued at £544,032, making a total in the past eight years, since the Walsh agreement, of £3,385,378. During the past year dividends were paid amounting to £178,000. Total dividends since 1903, £1,285,000.

MONTANA-TONAPAH MINING CO.

The annual report of the Montana-Tonopah Mining Co. for the fiscal year ended August 31, 1910, has been recently issued. It shows that during the year 50,245 tons was mined, all of which was milled. This ore had a gross value of $15.22 per ton, which returned in the mill $650,405.11. Total expenditures amounted to $515,689.71, leaving a net profit of $134,715.40. No custom ore was milled during the year. In addition to mining and hoisting over 50,000 tons of ore, 19,000 tons of waste was hoisted and trammed to the dumps, although the greater part of the waste resulted from development amounting to 10,861 ft. Labor costs were distributed as follows: Breaking ore, 84.4c. per ton; timbering, 2.11c.; hoisting and dumping, 25.4c.; blacksmithing, 3.8c.; surveying, 3.9c.; foremen and bosses, 7.5c.; sampling, 1.9c.; assaying, 2.7c.; sorting and shoveling, 61.8c.; tramming, 33.7c.; watchmen, 1.4c., and storekeeper, 1.1c. per ton. Supplies cost as follows: Breaking ore, 39.2c. per ton; compressed air, 10.8c.; timber, 20.1c.; hoisting and dumping, 8.4c., and hoisting-electric, 12.5c. per ton. Development cost $84,388.72, or $1.836 per ton of ore handled. Milling cost $174,445.80, or $3.798 per ton. The report appears to be complete, giving much of the detail of operations in both mine aad mill, which too often is lacking in company annual reports.

FEDERAL MINING & SMELTING CO.

The report of this company covering the operation of its Coeur d'Alene mines through the year ended August 31, 1910, is frank, though not particularly encouraging. The company is in metallurgical difficulties at the Morning, its leading mine. The reserves here stand at 543,000 tons, but a change in the character of the ore makes it uncertain how much will be realized. Experiments with Macquiston tubes are in progress. If no suitable method of treatment be found, W. Clayton Miller, the general manager, recommends that this particular mine be closed rather than waste ore reserves carrying 7 to 8% lead by recovering only 60%. If the recovery can be brought up to the customary 80%, the mine will do well. At Wardner the reserve is 313,600 tons, abont equal to two years' supply, making an average of 41,080. At Mace the reserve is 234,675 tons, about one year's supply. The reserve decreased 33,305 tons within the year. Settlement of the litigation between the Federal and Bunker Hill companies was effected within the year and the preliminary trials of cases arising from alleged damage from tailing in the streams have been decided favorably to the company. Suits brought by the Government to recover for timber have been satisfactorily adjusted. The profits from production amounted to $745,053, the total value of the output being $4,757,468. From stocks owned by the company and other sources the total income was brought up to $830,201. Dividends were paid on the preferred stock to the amount of $839,027, and the surplus balance was $1,015,109. Mr. Miller recommends the purchase or development of other properties in order to assure the future of the company.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

FAILURE TO PERFORM STATUTORY DUTY—ASSUMPTION OF RISK

A miner in a coal mine does not assume the risk of danger by continuing service as a miner where the owner or operator of the mine has failed to perform a statutory duty; and in an action for an injury caused by the failure to perform such statutory duty the complainant need not negative the miner's knowledge of such dangers.

Vandalia Coal Co. *v.* Yemm, (Ind.) 92 Northeastern 49. June, '10.

LOCATION OF MINE ON PUBLIC MINERAL LANDS—MARKING BOUNDARIES

The United States statutes provide that locators of all mines on the public domain so long as they comply with the laws of the United States and with the State and local regulations not in conflict therewith, shall have the exclusive right of possession. They also provide that miners of each mining district may make regulations not in conflict with the laws of the United States or with the laws of the State. Such statutes grant authority, by inference, to the State to add to the general location requirements when not in conflict with United States laws. Accordingly where the United States statutes require that, when a discovery has been made within the limits of the claim sought to be taken, the location be distinctly marked on the ground so that the boundaries may readily be traced and the record of the location shall contain the names of the locators together with a description of the claim by reference to some natural or prominent monument as will identify the claim, the requirements of the Colorado statute providing that before the filing of a location certificate the discoverer shall locate his claim by posting a notice thereon and marking the surface bonndaries with substantial posts at each angle of the claim, are valid and are not in conflict with the Federal statutes but merely add to its general terms.

Saxton *v.* Perry, (Colo.) 107 Pac. 281. Feb. '10.

CONTRACT FOR LEASE OF MINING LANDS WITH OPTION OF PURCHASE

A land owner entered into a contract with a corporation for a lease of land for the purpose of mining with an option to purchase the same and, in case of purchase, the first payment was to be made at a stated time and the deed to be executed when such payment was made. The contract or lease provided that the lessee should pay rent on the buildings and royalties on all the iron mined. Before the first payment became due a new contract was entered into by which the first payment was greatly reduced, the deed to be made as under the old agreement, and the new contract provided that the corporation might retain possession of all parts of the premises as were then occupied, and pursue the business of mining for ores "during and until this contract is finally consummated as contemplated on the first day of September 1907." The mining operations were continued after the execution of the second contract the same as before, but no payment was made and no deed executed; however, the owner received the royalties thereafter until the operations of the mine were stopped for lack of funds, and a chattel mortgage given on all the mining machinery. In an action for an injunction by the land owner to prevent such lessee from removing the mining machinery and tools from the mine and land, it was held that the second contract would be construed as a lease with option to purchase, though standing alone it was a contract for the sale of land; and on this construction the lessee could mortgage or sell the machinery as personalty, and under the lease as the tenant at the expiration of the option was a tenant at will he had the right to remove all mining machinery placed on the land which did not become fixtures after the termination of the lease.

Powell *v.* Plank, (Mo.) 125 Southwestern 836. Feb. '10.

ILLINOIS COAL STATISTICS

The following statistical statement of the coal mines of Illinois for the years ended June 30, 1909 and 1910, by David Ross, secretary of the Bureau of Labor Statistics for Illinois, is of unusual interest. The output for 1910 is but little below that of the previous year, notwithstanding the suspension of mining for three months owing to labor troubles. It is evident the mining equipment is for an advance of present requirements. Aside from the Cherry disaster, in which 259 lives were lost, the fatalities were below those of any previous year since 1892.

	1910.	1909.
Number of counties producing coal..	55	55
Number of mines and openings of all kinds	881	886
New mines or old mines reopened during the year	86	81
Mines closed or abandoned since last report	91	117
Total output of all mines in tons of 2000 lb.	48,717,853	49,163,710
Number of shipping or commercial mines	390	384
Total output of shipping mines, tons.	47,225,201	47,958,562
Number of mines in local trade only.	491	502
Output of local mines, tons	1,492,652	1,205,148
Total tons of mine-run coal	10,220,456	8,715,759
Total tons of lump coal	20,769,930	21,680,602
Total tons of egg coal	3,334,059	3,444,612
Total tons of nut coal	2,846,693	2,944,036
Total tons of pea coal	10,174,617	10,587,057
Total tons of slack coal	1,372,038	1,791,644
Total tons shipped	43,007,015	43,894,902
Tons supplied to locomotives at the mines	886,217	1,023,294
Tons sold to local trade	2,867,871	2,316,778
Tons consumed (or wasted) at the plant	1,956,750	1,928,736
Average days of active operation for shipping mines	179	189
Average days of active operation for all mines	171	168
Average value per ton all grades at shipping mines	$1.016	$1.012
Aggregate home value of total product	$50,204,207	$50,303,757
Average value per ton all grades at all mines	$1.031	$1.023
Number of motors in use underground	216	210
Number of mines in which mining machines are used	114	107
Number of mining machines in use..	1,291	1,246
Number of tons undercut by machines	18,176,254	16,407,692
Number of tons mined by hand	30,541,599	32,756,018
Average number of miners employed during the year	39,069	50,834
Average number of other employees underground	28,137	13,788
Average number of boys employed underground	1,154	1,752
Average number of boys employed above ground	47	71
Average number of other employees above ground	6,227	6,288
Total number of employees	74,634	72.733
Number employed at shipping mines	71,520	69,518
Number of persons at work underground	68,360	66,374
Number employed at local mines	3,114	3,215
Number at work on surface	6,274	6,359
Average price paid per gross ton for hand mining, shipping mines	$0.597	$0.593
Average price paid per gross ton for machine mining	$0.462	$0.460
Number of kegs of powder used for blasting coal	1,254,095	1,280,607
Number of kegs of powder used for other purposes	3,128	3,963
Number of men accidentally killed (Cherry mine disaster, 259)	390	213
Number of men injured so as to lose a month or more of time	737	894
Number of gross tons mined to each life lost	124,917	230,816
Number of employees to each life lost	191	342
Number of deaths per 1000 employed.	5.2	2.9
Number of gross tons mined to each man injured	66,103	54,993
Number of employees to each man injured	101	93
Number killed to each million tons produced	8.0	4.3
Number injured to 1000 employed	9.9	10.7

LEAD AND ZINC prices at Joplin recently have improved. Although $47.50 was the base price for 60% zinc ore last week in the district, some selected ore sold as high as $49.50. Zinc silicate sold at $24 to $26 per ton for 40% ore. The average price for all grades was about $42.80. The highest price paid for lead ore was $54 per ton. The total value of zinc and lead ores from the district for the first 46 weeks of the year is in excess of $12,175,000.

THE OCTOBER TRADE STATEMENT shows that during October total imports amounted to $123,869,000; total exports during the month were $208,757,000. In the first ten months of 1910, imports amounted to $1,296,245,000, and exports to $1,430,968,000, showing an excess of exports over imports of $134,723,000. Exports reached a higher figure during the first ten months of this year than any similar period since 1907.

COBALT, the famous silver district of Ontario, Canada, will have output during the year 1910 about 2,000,000 oz. more than in 1909, while the total selling value of the year's production will probably reach $3,000,000 more than last year. The total output for 1910, it is estimated, will reach 31,700 tons of ore, containing 27,259,420 oz. silver, valued at $14,720,000. The increased price of silver is materially aiding the profitable operation of Cobalt mines.

The GOLDFIELD CONSOLIDATED mine closed its fiscal year October 31. During the year the gross output was $10,850,000 in gold, making it the largest single contributor to the gold output of the world. Dividends to the amount of $7,117,696 were paid, which placed it at the head of the list of gold dividend paying mines. The net earnings exceeded dividends by $287,915. At the close of the fiscal year the company had in cash and bullion about $2,000,000.

THE VISIBLE foreign copper supply shows a material falling off, it having been reduced about 60,000,000 lb. since March 1 last. There was a decrease during the first two weeks of November of 3,837,120 lb. On November 15 the total foreign visible supply was 194,228,100 lb. From July 1 to November 1 the total world's supply decreased from 401,139,697 to 339,327,194 lb., being about 16% in four months. The supply of copper in the United States is decreasing as well as that abroad.

THE IRON INDUSTRY has long been considered by many as the most reliable index of the industrial condition of the country. At present the production is decreasing, iron in some instances selling below cost, so it is stated. Such cases are probably exceptional, however. Last February the furnaces of the country were producing at the rate of 85,616 tons per day. In October the rate of production was 67,335 tons per day, and in September 68,476 tons. It is stated that the November production will be still lower than that of October, due largely to the banking of furnaces operated by steel companies. In 1909 the total production was 25,795,474 tons. The total for 1910 is estimated at 24,677,275 tons.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

THOMAS T. READ is in London.

VICTOR BRASCHI is in New York.

W. E. DEFTY is now in Sonora, Mexico.

KARL EILERS was in San Francisco Tuesday.

E. B. KIRBY was in San Francisco this week.

R. H. CHANNING was in San Francisco Tuesday.

C. C. BROADWATER was at Los Angeles this week.

L. G. PERRIN, of Twin Falls, Idaho, is in San Francisco.

WILLIAM KNOX is back in San Francisco from Brazil and London.

W. H. LANAGAN has returned to San Francisco from Nome, for the winter.

GEORGE OTIS SMITH has returned to Washington, D. C., from California.

M. M. JOHNSON, of Salt Lake, has gone to Ely to inspect the Ely Central.

H. M. THOMPSON, of Redding, California, was in San Francisco this week.

J. R. PEMBERTON will go to the Argentine Republic to make geological surveys.

ALFRED FRANK, formerly of Butte, is manager for the Ohio Copper Co., Bingham district, Utah.

W. J. ELMENDORF is manager for the Portland Canal M. Co., operating at Stewart, British Columbia.

GEORGE SKEAVINGTON, superintendent at the Tajo de Dolores mine, Guanajuato, Mexico, is in New York.

HENRY KRUMB, consulting engineer for the Inspiration Copper Co., Miami, Arizona, has returned to Salt Lake.

H. V. WINCHELL is expert witness for the Anaconda, and W. H. WEED for the Butte-Ballaklava company in litigation at Butte.

A. C. VEACH, A. R. SCHULZ, and E. E. SMITH have resigned from the U. S. Geological Survey to go to Venezuela for the Barber Asphalt Company.

WILLIAM R. JEWELL has returned to Bakersfield from Sacramento, California, where he has been engaged as expert witness for the defendants in the case of the United States *v.* H. N. Brown, involving placer property in Plumas county.

THE SAN FRANCISCO SECTION of the Mining and Metallurgical Society of America gave a dinner in honor of George Otis Smith, Director of the United States Geological Survey, at the Palace Hotel, November 22. Those present were Messrs. G. O. Smith, A. C. Lawson, W. C. Ralston, W. H. Metson, W. H. Lanagan, C. H. Munro, Ross B. Hoffmann, Charles Janin, C. G. Yale, Charles Butters, E. B. Kirby, F. G. Cottrell, E. A. Hersam, F. G. Kay, William Forstner, T. L. Oddie, W. P. Hammon, M. L. Requa, A. F. L. Bell, John Barneson, S. W. Morshead, Frank Griffin, E. H. Benjamin, E. C. Hutchinson, C. T. Hutchinson, J. A. Taff, G. D. Louderback, L. J. Pepperberg, Chester Naremore, and H. F. Bain.

CHARLES H. TUCKER, secretary and treasurer of A. Leschen & Sons Rope Co., St. Louis, died at Clifton Springs, New York, Sunday afternoon, October 30. He was one of the best informed and most extensively known men in this country identified with the wire rope industry. Mr. Tucker was born in New York City 50 years ago. While yet a young man, he entered the New York office of John A. Roebling's Sons Co., advancing steadily in their service until 1898, when he went to the firm of A. Leschen & Sons Rope Co., with which he remained until his death. Mr. Tucker became ill on the train while on a short business trip to the Pacific Coast in July, but with characteristic determination finished his business. He was a man of great ability and his death will be widely regretted.

GEOLOGY AND ORE DEPOSITS OF HEDLEY MINING DISTRICT, BRITISH COLUMBIA. By Charles Camsell. Canada Department of Mines, Geol. Surv. Branch. Memoir No. 2. Pp. 218. Ill., index, maps. Ottawa, 1910. A description of the valuable Nickel Plate mines and their development, together with description of the tramway 15,000 ft. in length and 4000 ft. difference in elevation between terminals. Other mines in the vicinity are also described.

COMPARATIVE STATISTICS OF LEAD, COPPER, SPELTER, TIN, ALUMINUM, NICKEL, QUICKSILVER, AND SILVER. Compiled by the Metallgeselischaft, the Metallurgische Gesellschaft A.-G., and the Berg und Metallbank, Aktiengesellschaft, Frankfort on the Main, 1910. Pp. 111. This is the sixteenth annual issue of this exhaustive compilation of the statistics of production and consumption of the metals named in the title.

MODERN MINING IN MICHIGAN

Development of the great deposits of iron ore in the Menominee range, in upper Michigan, is progressing rapidly. Some of the most important mines of that region have been heavy producers for 25 years and will continue to make a large output for many years more, as determined by the systematic boring by means of diamond-drills. One of the mines which promises to develop into a large producer is the Buckeye, owned by the Reserve Mining Co. Its output in 1909 was only 50,000 tons, but this will be more than trebled the present year, and succeeding years will see the output largely augmented as more extensive development makes greater output possible. The mine workings are a mile and a half south of Commonwealth, Wisconsin. The ore is medium hard hematite, running well in iron content, and of excellent grade for furnace work. It breaks in good-sized lumps, which makes it desirable to mix with the fine ore of the Mesaba range. A single-compartment shaft has been sunk 300 ft. and stoping is in progress on three levels. The shaft will be sunk 200 ft. during this winter and levels opened at 400 and 500 ft. The ore is mined by back-stoping. From the main-level drift, raises are driven to a height of 15 ft. and timbered for use as chutes. One raise is driven from level to level for ventilation. The ore is broken into the chutes, and the pile carried up almost to the level above. In this way about two-thirds of the ore can be stocked in the mine during the winter months. When the stopes are finished, the ground left between the levels is shot down into the chutes. The manways are carried up in the rock, and small drifts opened into the stope as the pile grows. This differs from some Western practice in which square-set timbered man-ways are carried up at either end of the stopes, sets being added as the pile grows higher.

Sullivan Hammer-Drill Block-Holing.

For breaking the ore, Sullivan 'UC' (2¾-in.) rock-drills are used exclusively, and the raises are put up with hammer-drills of the same make. These latter drills are also used to good advantage for breaking up boulders in the chutes. Instead of laying powder on the fragment to be broken, and thus risking damage to the chute, block-holes are drilled as shown in the illustration. This also results in a saving of powder. When the shaft is continued from one level to another, a winze is sunk in the ore some distance from the shaft to the lower level. Then a drift is run to a point directly under the shaft, which is then 'raised' with hammer-drills.

TABLE OF CONTENTS

EDITORIAL

THE WINTER MEETING of the Geological Society of America will be held at Pittsburg, Pennsylvania, December 27 to 29. Mr. Arnold Hague will preside and the sessions will be held in the Carnegie Museum.

RENEWED activity on the part of the United States postal authorities against certain promoters of mining, oil, and other stocks, the merits of which have been grossly misrepresented to the public through the medium of the mails, is gratifying.

NOME is described most interestingly in the mining and dredging edition of *The Nome Daily Nugget* of October. Readers of this handsome special issue can not but be impressed with the fact that the era of great dredges which has supplanted that of the pan and sluice, is likely to be long and profitable.

THE HECLA MINE at Burke, Idaho, is one of the most interesting properties in the Coeur d'Alene district. Discovered by poor men and with but small initial capital, it has paid a total of $2,070,000 in dividends and evidently has a prosperous career still in store. In our news columns recently the amount of the total dividends was misstated, and we are glad to make this correction.

CALCULATION of recovery in concentration, where there is no opportunity for making a complete mill test, must often be undertaken even though the result is necessarily of but approximate accuracy. Formulas for making such calculations have recently been published by Mr. Theodore J. Hoover in *The Mining Magazine* and the *Engineering and Mining Journal*. Messrs. Dietz and Keedy have shown that the formula employed by Mr. Hoover is not new and state that they have used it for "the past five or six years." They further say that Mr. Rudolph Gahl, of Morenci, Arizona, proposed the same method of calculation "about a year and a half ago." In view of these facts it is interesting to note that in the issue of the *Mining and Scientific Press* of September 21, 1901, there was a contribution by Mr. Jesse Seobey under the title 'Sampling Mill Work' in which the matter was discussed and formulas were given which are esssentially the same as those employed by Messrs. Hoover, Dietz & Keedy, and Gahl. Evidently the method of calculation is not new, and Mr. Seobey deserves the credit for having first called attention to its usefulness.

GUSHERS continue to be found in the Midway-Sunset oilfield of California. The latest is the Midway-Premier, which came in about three weeks ago. After a week of most difficult and trying times, during which the well flowed approximately 40,000 barrels of oil per day, it was brought under control November 17. Open reservoirs were at once constructed and when the well broke loose a second time the following Sunday arrangements had been made to care for 750,000 barrels. If the well can not be again controlled quickly, even this storage capacity will be exhausted. The Lake View is flowing steadily and though some of the oil is being moved, the Lake View company has nearly three million barrels in reservoirs. Since other gushers may be brought in at any moment, or those now flowing may cease to do so, it is not surprising that the future price of oil in California is uncertain.

Alaska and Its Problems

Alaska and its needs are discussed with keen insight in the report that Mr. W. E. Clark, the Governor, has made to the Secretary of the Interior. Mr. Clark, while but new to Alaska, is a trained observer and writes with a trenchant pen. He sees the needs of the district and tells about them in a way to attract attention. We trust that Congress may not be too engrossed in routine business this winter to act on his recommendations. Fundamentally, cheap fuel and better transportation facilities are the things most needed. The two are closely related. Better transportation facilities means more railroads, and the latter cannot be built or operated without cheap fuel. At present the coal so abundant in the area cannot be mined because of legal complications regarding titles. This situation should be remedied promptly regardless of the fact that so long as California continues to supply cheap fuel oil, Alaskan coal is not likely to make great headway in Pacific Coast markets. For use at home, however, and specifically for burning in locomotives reaching the coalfields, it is needed; and ways should be promptly found for permitting it to be mined. It seems clear that the tangle regarding existing claims on Alaskan coal lands will not be settled except through long-continued litigation. The issues have become so confused that any executive action would be considered arbitrary and unjust by one or the other parties to the controversy and the whole matter should be given to the courts for adjudication on the basis of law and evidence. At present there is no legal authority for throwing the matter into the courts, though such a solution of the difficulties has been recommended by the Secretary of the Interior. Congress could do no wiser or more popular thing than to promptly provide a means by which these and similar cases could be passed on by a suitable court. It should be remembered, however, that not all the coal in Alaska is covered by the Cunningham and other claims, and that for some years now it has been impossible to acquire coal or coal land in the District on any legal basis. In the meantime, fuel must be imported to carry on all enterprises, including even construction work on railroads to the coalfields. Mr. Clark suggests that a leasing system be established so that it may be possible at once to open such coal mines as local conditions warrant. It is known that Mr. Taft and Eastern leaders in the conservation movement are favorable to this suggestion, and it has this great merit, that if on trial it be found less satisfactory than is anticipated, Congress can at any time enact legislation converting the leases into fees. A leaseholder would be willing to receive the present of full title to the property, while if fee be now given it will be impossible, except by condemnation and purchase, to convert the full title into a leasehold. The conservationists have insisted that it is not now necessary to give everything away in order to secure development. Many of those familiar with conditions in Alaska and the risks involved in investment there, doubt whether the new doctrine is applicable so far away. Probably nothing short of trial will convince the members of either party. Under these conditions Mr. Clark's suggestion is particularly to be commended. Under a leasing system it should be possible to open such mines as are now really needed without undesirably committing the Government for the future. Naturally, the leases should be extremely liberal as to terms.

It is worth recalling that at one time Mr. Roosevelt and officials of the Department of the Interior favored such a system for the remaining coal lands in the Western States and Territories. The principal good expected to be accomplished by introducing it was the prevention of monopolization of coal lands by speculators. Congress, however, considered the change too radical and refused to enact the necessary legislation. Instead, the system of valuing the coal lands as surveyed, and selling them at the prices fixed by the U. S. Geological Survey, was inaugurated. In practice this has worked excellently. While the new prices, although flexible, average much higher than the old flat rates, experience has shown that they are not so high as to discourage development; indeed, the fixing of a price after examination and survey establishes confidence in the value of the lands and makes it easy to secure money for them. As a result, sales in certain districts are more numerous than before. On the other hand, the prices are so high that there is no money to be made by buying lands and holding them for speculation. It is easy to get such coal land as is now needed and money to pay for it, but unprofitable to buy and hold the land for the future. An interesting side-light on the way the system works is thrown by the fact that in eastern Kentucky there are now large areas of excellent coal land which, because their value is not known, can be purchased at about $17 per acre. The same land situated in Montana or elsewhere on the public domain would be valued by the officers of the Geological Survey at $300 or more per acre. The Kentucky land may be profitably purchased for speculation; the corresponding public land cannot. In either case, if a present demand for coal exist, it would be profitable to buy the land and open a mine. Mr. Alfred H.

Brooks, whose opinion regarding Alaskan matters is entitled to peculiar respect, has suggested that this system be extended to Alaska: that the land be priced at its actual value, and sold in tracts of reasonable size as fast as needed for development. In his judgment the flat price fixed by the old law is much too low in certain cases and equally too high in others. This system has the merit of involving less change from old methods than does leasing and has the further advantage of having been tried and found to work well in the States. While personally favoring the leasing system for the remaining public coal lands, we believe that Alaska should be given every opportunity for development that is afforded to the Western States and Territories. If there be any difference, Alaska deserves more rather than less, and, pending a satisfactory general solution of the problems involved, a system that has been found satisfactory here may be safely extended to the northern District.

Cheap fuel is not the only need of Alaska. It is a means rather than an end. Cheaper and more reliable transportation is equally important, and to that end railroads must be built much more generally. While the country is unusually blessed in the matter of coast and inland water routes, it should be remembered, what many earnest advocates of river reclamation forget, that for most classes of freight steamboat transportation is expensive. It is only where transport in bulk is possible and freight movement extensive and steady that inland water transportation is economical. For ordinary package freight, railroads are superior. We have already published examples of existing freight rates in Alaska that illustrate how heavily industry there is burdened by transportation charges. The amount of freight known to be available is, however, small, and the exact increase to be expected no man can accurately state. Railroad building in the Far North is necessarily an uncertain business, and capital hesitates when asked to undertake other than short lines where traffic is sure. We have already expressed our belief that building a certain number of trunk lines is a National duty. Mr. Clark recommends that the Government guarantee bonds covering construction of such lines as may be agreed upon between agents of the Government and constructing companies. It would seem to us better to adopt some such plan as is now in operation in the Philippine Islands. There is a well grounded opposition in America to the old plan of lending the Government credit to private or quasi-private enterprises while leaving to individuals the whole of the contingent profits. If the people guarantee the investment, why not give them a share in the profits? A plan whereby the constructing company makes its profit out of the operation of the road through a term of years, eventually turning the property over to the Government to operate or to lease to an operating company, as then seems to be best, is fair to all concerned. Whatever plan may be adopted, however, the essential thing is that the United States recognize its duty to provide Alaska with adequate railroad lines. The National credit was drawn on to build the pioneer roads to the Pacific Coast and the whole country has gained greatly as a result. If the particular plan adopted in the sixties has proved faulty, a better one should be devised. There is as much obligation to connect the interior of Alaska with the coast as there was to give California and the Mississippi Valley easy means of communication.

The Governer's other recommendations are equally pertinent and, in the main, sound. His objection to staking ground by use of power of attorney will prove popular in Alaska, whatever attention it may or may not receive at Washington. There are good arguments in favor of the system, but the fact is that in practice it works injustice to the man on the ground and hampers development. It should be limited, if not abolished. Whether Alaska is ripe for independent local government is a matter about which opinions differ. The present system has many serious drawbacks, but so, too, would one involving legislation by an assembly composed of individuals resident in towns as widely scattered as are those of Alaska. Under present conditions a commission form of government such as recommended by the President would have many advantages, if the right sort of men were made members of the commission. The proposal is, however, undeniably unpopular in Alaska, and in the States there is great doubt whether a commission would not lead to exploitation rather than development. Probably no fundamental change will be made until the situation becomes clearer and the facts are better understood. In the meantime, Alaska has evidently an intelligent and trustworthy friend in its present Governor.

Honduras in Revolution

Observerers of affairs in the Central American Republic, and particularly in Honduras, cannot have failed to notice the facility with which a full fledged revolution can be launched there, and the equal promptness with which it can be ended. It requires little beyond ambition and a strong personality for any citizen to secure a following in that Republic, and the smallest matter may be considered by the disgruntled politician as a *casus belli*. One of the most serious revolutions with which Honduras ever had to deal was caused by a dispute over a division of the spoils incident to the operation of the Lonisiana lottery in that country. At present Señor Valladares has thought it a psychological moment to 'start something' which might add to his political power, and place him at the capitol in the presidential chair. He has seized the fortified island on which is situated Amapala, the only port of entry on the West Coast, and has secured quite a following of the bare-footed soldiery. His chances of being shot are excellent, notwithstanding his claims to the presidency. Honduras has great, though almost wholly undeveloped, mineral resources, but until these frequent riots, dignified by the name of 'revolutions,' cease, the resources will remain untouched, for the reason that capital is not willing to assume the additional risks which the unstable government of that country involves.

BY THE WAY

The following, a portion of an essay on 'The United States and Mexieo,' written by James Douglas and published by the American Association for International Conciliation, will be read with especial interest at this time. Mr. Douglas' thorough familiarity with Mexico and his high eharaeter lend emphasis to all that he says.

As a miner the Mexiean possesses manual dexterity of a high order, but it requires time to eradicate the old habits of mine working, whieh he and his forbears have aequired through generations of practiee. Around a furnaee he is at home. Like all dwellers in a tropieal or semi-tropieal elime, he has never felt the neeessity of steady work, and therefore has never habituated himself to it; but he rapidly learns to diseard sandals and wear shoes, and to imitate the higher standards of living of his northern fellow-workers. He soon learns that to maintain that position he must make money and work steadily. He therefore abandons his erratie habits. If the managers of foreign eompanies would temporarily submit to some ineonvenience and annoyanee, involved in employing more Mexieans and fewer foreign workmen, they would before long not only find it to be to their profit, but they would help to alleviate the smouldering feeling of jealousy and dread whieh can be used so widely and sueeessfully by sueh agitators as wish to use the *pro patria* movement for politieal purposes.

There is no denying that a dread of the overwhelming strength of the United States has always possessed the Mexiean mind. Don Pablo Maeedo, in his chapter on Railroads, tells us of the eonferenees whieh preeeded the adoption of the railroad poliey in Mexico. He says: "In deciding on the gauge the truth is that the question was diseussed, whether or not they should aeeept the gauge adopted by their neighbors of the Northern Republie. It was a consideration of the gravest moment, and transeended all others. No one, and still less statesmen of the status of Señor Lerdo de Tejada, has ever been blind to the danger that we run from the nearness of our colossal neighbors on the north. In comparison with the United States—more's the pity—we must confess that we then figured, and we still do, as a mere pigmy. Besides this the sad memory of the iniquitous war of 1847, which eost us the half of our territory, is more than enough eause to excite uneasiness and even dread. Sueh apprehension is certainly not unreasonable or groundless. As a consequence, the distinet objeet of our international poliey has neeessarily always been, in the first plaee, to grow by natural expansion, to fortify our national organisms, and then to seek from the other side of the Atlantie a support whieh alone ean be efficacious by creating, aeelimatizing and strengthening European interests and elements. Unfortunately, the unjustifiable Freneh intervention, obliging us to sustain a war *à l'outrance* in order to preserve our very existenee as a nation, interrupted our organie development, and not only weakened our position physieally, through the material sacrifiees which we had to make, but morally by creating divisions greater than had previously existed. The blood of Maximilian created an abyss between Europe and Mexico. His death, though it may have been the only means, sad as it was, of securing internal peaee, estranged the sympathies of those nations which then exercised preponderating influenee in Europe." (*La Evolution Mercantil por Pablo Macedo*, page 199.) The above extraet probably expresses correetly the prevalent feeling among the edueated elasses in the past and in the present. And it is they alone who can exert politieal power; for though the franchise is universal, under the Constitution of 1857 and the electoral law of 1901, the vote is really east by an electoral college, eomposed of one elector for each 500 inhabitants, and the members cannot be supposed to know the wishes of their constituents as distinetly as those who vote for the President of this country.

Universal suffrage, therefore, in Mexieo does not voiee the popular will as distinetly as it does in this eountry; but from one motive or another there is an almost universal and reasonable dread of offending this eountry, under the belief that the consequenees might be disagreeable and fall with lightning speed. Every eitizen of the United States who enters the Republic for the transaction of business or to engage in industrial pursuits, through some indiseretion of his own or through some arbitrary aet of over-zealous Mexican official, may give rise to international complieations. These risks are greater by far in a sparsely settled country like Mexico than in a land where the provineial government is thoroughly organized and under striet control of the eentral power; and it is diffieult to maintain perfeet order and to mete out perfeet justiee where the officials eannot possibly be men trained for their posts. In this rapid influx of foreign eapital, under foreign management, the Mexiean sees therefore cause for anxiety whieh is in itself a source of danger; and it cannot be wondered at if their sensitiveness is increased by the memory of the original Texas diffieulty, and the fact that till reeently the border population from the Atlantic to the Pacifie, possessed of irresistible energy, found vent for it sometimes in eeeentric enterprises which were not suggested by the State Department. Most wars have originated in trade disputes or eommercial jealousy; and so ready are our frontiersmen to avenge any injury or insult that they have not waited for deelarations of war before taking the law into their own hands. There have been instances even recently where armed bands have crossed the line to foreibly maintain what they conceived or at any rate elaimed to be their rights. Besides which, there are people—presumably well intentioned—north of the line, who, eomparing political eonditions in their own country with those prevailing in Mexico, consider that interferenee in favor of their neighbors is a duty. They do not always weigh the differenee in the habits and education of the voters, which this arbitrary boundary divides; and that truer liberty may eoineide with limited rather than with unlimited franchise during a certain stage of a people's soeial and politieal development.

Old-Time Mining Schools and Mining

By W. C. Wynkoop

It is questionable whether during the past fifty years advance in any branch of science, tremendous as it has been, has been greater than in educational facilities in mining and metallurgy. At the same time, it is not certain that the methods of teaching have not lost as well as gained. In the old days, because facilities were lacking, there was greater necessity than now for search for authorities; and hot discussions, in and out of the class-room, took much of the place of data now furnished ready-made to the student. Many a wit was sharpened by these discussions, and many a habit of research formed. Fifty years ago there was one mining journal in the United States. There were no mining schools, designated as such: there were no Geological Survey reports and no publications of mining or scientific societies, and no such voluminous mining literature as now which makes it a physical impossibility for one man to separate the wheat from the chaff. It is pleasant to look back, both as student and teacher, and linger in the ruins of the old halls, among the old books, lessons, and work; and their spirit sometimes returns to nerve one to renew youth. The old schools gave little instruction in mining and metallurgy, partly because the spirit of science was not yet awake, but mostly because there was little or no demand for it. Some gave instruction in surveying and chemical laboratory work. In surveying, the present does not seem to have improved on the old methods of teaching. The latter gave an abundance of field work and more in astronomical observations and astronomy than is usual now. In those days the light transit had not been developed: weight in the instrument was considered essential to accuracy. One of the first instruments I used weighed more than thirty pounds. A Confederate sharpshooter permanently knocked it out of commission, and no bullet ever gave me greater satisfaction, unless it was one deposited where it would do the most good in an Indian.

When a boy at the proper age to know everything and then some, I was one of a class which was getting instruction in surveying. Then came the Civil War and I joined others for a ninety-day frolic in the army, which proved to be anything but a frolic, and the ninety days stretched into more than four long weary years. At the end of the war there had been an entire revolution in the course of study in many of the colleges. Holes had been broken in the fence of prejudice which had surrounded progress. The fetish of the classics had died at the same time as did slavery, and the age of science had been ushered in. The first school of mines in the United States to give a degree of mining engineer had been established in Columbia College, and most higher institutions had established courses in science, though they gave no E. M. degrees. The course was in civil engineering with elective studies which were to prepare one to do mining work. These courses consisted of engineering, chemistry with laboratory work, mineralogy, and as much as possible, which was little, in mining and metallurgy. Mechanical and electrical engineering were in the future. The metallurgy taught was almost wholly of iron and steel, and it bore about as much relation to their metallurgy of today as the ox wagon does to the automobile. In the chemical laboratory the instruction was thorough, but it included nothing of electro and spectro-chemistry. Electric science was not born. The determinations were gravimetric. The volumetric methods were used only for iron and copper, though for both students were also taught to make fire assays. For the latter the method was brought from Swansea, and was used, at one time, to a slight extent on the ores of Lake Superior. In the hands of a master, on ores containing metallic copper, it was claimed to be fairly accurate. It took two days to make a zinc determination, and the many quick methods in use in laboratories had not been developed. If it were necessary to go back to the methods then in use every smelter would require an army of chemists. Accuracy was demanded, and the sloppy student was given a chance to reform, and was given a permanent vacation from the laboratory if he did not do so. Fresenius' book was then, as now, the great text. In mechanics there was a text-book on natural philosophy, with few illustrative appliances in the physical laboratory, where there was such a thing. Especial attention was given to the steam engine. Some schools had a small model of a Cornish jig, a buddle, and perhaps a Rittenger table, but object lessons or practical work in metallurgy were impossible. I supposed concentration was a very simple mechanical operation, devoid of difficulties. It seems to be generally considered so now in California, where the concentration floor is often under the charge of the cheapest labor in the mill. In most of the Rocky Mountain country the most skilled and highest-priced labor is none too good for that job.

The joys of the course were mineralogy and geology. The latter furnished plenty of opportunity for intellectual contests. The science was comparatively new, and discussions about it were often tinged with bigotry and bitterness. Agassiz' theory of the glacial period was only twenty years old, and Darwin's theory about the origin of species was half a dozen years young. Many professors were orthodox preachers, and it was difficult for them to accept the teachings of the geologists. Sermons were thundered from many pulpits denouncing the science which destroyed the theory that the world was only six thousand years old. One noted and learned bishop compared a geologist to a gnat on an elephant, laying down theories about the whole internal structure from the phenomena of the hide, and the whole theological world seemed to think his comparison settled the tribe. Geologists were sometimes ostracised and classed with infidels, and to be an infidel was as bad as to be a criminal. Agassiz opposed Darwin's theory wholly on account

of a missing link in the fossil chain. It was remarkable how he seemed to gain popularity among theologians where he had lately been so unpopular. Some of the wilder students formed a society which they called the Missing Link, and they did such a large and well-assorted lot of things to the proprieties that the president said they were well named, because they were neither Christian nor human, but belonged to the monkey tribe. Many of them for years afterward answered to the nickname of Monk. They adopted a monkey head painted on a cork for a badge. This before long was changed to the famous elk head, and the 'monkey shines' which characterized them at first were changed to something better. College boys tipped over Diogenes' tub, and they will probably continue to tip over tubs as long as there be any.

Looking back at the bitterness of the theologians toward geology, it is not difficult to understand the Inquisition. Grand old Hugh Miller wrote 'The Testimony of the Rocks' and blew out his brains after going insane trying to reconcile the Mosaic account of creation with geology, and one great preacher declared that his act was justified by his impious book. Of mining geology there was little except what was found in the general works. Phillips' ancient work, which was chiefly remarkable for generalizations drawn from insufficient data, was standard. He divided veins into two classes, one of which cropped above the ground and the other which did not, and one of them, I have forgotten which, was pretty certain to be worthless. Van Cotta's classic work was unknown, and there were but faint echoes from the academic groves of Freiberg. What mining was taught dealt almost entirely with coal. Students were told that the maximum depth to which it was possible to sink a shaft was sixteen hundred feet. Having seen something of shafts, drifts, and stopes, I was sometimes called on by a teacher whose practical knowledge of quartz mining was preceded by the minus sign, to tell how some of the work was done.

The years following the Civil War were noted in the Rocky Mountain country, where the ores are more complex and 'refractory' than they are west of the Sierra Nevadas, for an enormous number of patented or secret processes, each of which was guaranteed to revolutionize mining. It was the golden age for humbugs. On account of the character of much of the ore some method of treating it was needed. There are always plenty of self-styled scientists to meet every need, if there is any money in meeting it. The only processes used in the United States were the ordinary stamp-mill, pan amalgamation, and one small Plattner chlorination mill in San Francisco. Smelting had scarcely come into use. Of the hundreds of processes which were born and died, lixiviation was the only one which had any degree of success, or which added anything valuable to the sum of metallurgical knowledge. Every one of the old mining camps in the Rocky Mountains is the graveyard of one or more of these processes. All the great improvements which have been made in smelting, concentration, and milling are the product of slow evolution and not of the inventor's brain. There has been almost, if not quite, as much change in mining and prospecting as there has in the correlated branches. The power-drill and high explosives had not been invented. Black powder only was used. Cartridge paper and a special soap which acted as a glue to assist in making a cartridge, were parts of every mining equipment. The fuse was poor, and tamping so as to avoid injuring it required skilful work. Almost every miner hunted up good clay and carried it with him to the mine for tamping. Missed shots were almost always picked out, and while resulting accidents were common, they were seldom fatal. When the tamping was loosened, as it was in picking it out, the black powder was pretty certain to blow out without breaking rock. Miners with black, powder-marked faces, often blind in one or both eyes, were common. Ore was generally measured by the bushel, as it is now measured in some parts of Colorado by the cord. On the Pacific Coast prospectors never suffered much from hostile Indians. It was far different in Arizona and most of the Rocky Mountains. A rifle and a good dog which would smell an Indian and give warning of his presence were essential parts of a prospector's outfit. Almost weekly there were reports of some who had been murdered by Indians, and if the poetic story of the recording angel be true, his books alone can tell of the many who went out in the morning and were never heard of again.

The copper mines of Lake Superior are wholly unlike copper mines elsewhere. The Lake deposits consist of beds of conglomerate and sheets of amygdaloidal diabase, and tuff containing native copper, generally in the form of finely disseminated grains, though occasionally masses of large size have been discovered which had to be cut up into pieces that could be readily handled. The ordinary ore is hoisted from the mines and sent to stamp-mills, where it is crushed and the metal recovered by concentration. The stamp-mills are of a type seldom found elsewhere, being what are known as steam-stamps. They are erected in heavy steel frames and set on massive foundations of concrete with anvil-blocks beneath the mortar, weighing twelve or more tons. The capacity of one of these stamps exceeds 500 tons of rock each twenty-four hours. Similar stamps have been tried at Butte, Montana, on sulphide copper ore, and at the Homestake, in South Dakota, on gold ore, but at both places their use has been discontinued.

The prospector is supposed to be neither a geologist nor an engineer, therefore the law requires him to locate his claim along the course of the vein at the surface, and not necessarily on the true strike as it would be proved by an adit run on the vein. Where veins dip less than 60 degrees from the horizontal and the country is cut by abrupt gulches or canyons, the apparent strike of veins at the surface may be very irregular, though the real course of the vein taken horizontally may be nearly straight.

Mining in the San Juan—II

By William H. Storms

In the San Juan region prospectors seem to have confined their attention to the search for those types of ore deposits with which they are most familiar, neglecting or failing to recognize the commercial possibilities of others. The types that have been worked extensively and successfully are impregnations in quartzite, replacement deposits in limestone, and the fissure veins. The latter are found in both

Tunnel Through Snow Near Ouray.

the older stratified rocks and in the later volcanic series. The most important veins occur in the volcanic rocks. In a number of places I observed masses of brecciated and silicified limestone which on close inspection almost invariably showed scattered grains and veinlets of pyrite, galena, and blende, indicating the possibility of the occurrence in these highly silicious ores of gold and silver, as well as the sulphides of the base metals. In physical appearance the deposits greatly resemble some of those found in the Black Hills of South Dakota, particularly those in the region about Ragged Top, and in Spearfish canyon near Carbonate. Careful investigation of some of these occurrences near Ouray might result in the discovery of ore sufficiently rich in precious metals to be profitably mined. It is a matter that should receive attention.

A fault, previously referred to, crosses Canyon creek and the Uncompahgre river in the southern outskirts of the town of Ouray, resulting in the uplift, on the south side, of the Ouray (Devonian) limestone, several hundred feet, where it is exposed at the Mineral Farm mine and in that vicinity. No prospecting of any description has been attempted in this limestone where it lies beneath the town of Ouray, although it is known to be mineral-bearing in this district in several places. It is not probable that ore may be found at every place where the limestone may be penetrated, but diamond-drilling would prove whether or not the limestone contains deposits of value underneath the town. Any ores found at that depth would undoubtedly be sulphide, and probably of a complex character.

In the southeastern part of Ouray, rising several hundred feet above it, and continuing for a mile or more beyond the town in an easterly direction, is a huge mass of rock detritus that has slipped down from greater height. Although it is covered with a dense thicket of brush, aspen, and pines, its character is still clearly evident, particularly where a stream has cut down through the mass of boulders, clay, and earth. There is no evidence to show that this great landslide has occurred in recent years, though it undoubtedly moved repeatedly, in masses of greater or less size, after the main slide came down. This is indicated by the curiously uneven topography of its surface, generally characteristic of landslide areas. Landslides and glacial moraines are scattered the entire length of Canyon creek, which joins the Uncompahgre in the southern outskirts of the town. Evidence of the former presence of glaciers in these mountains is abundant. In many places the hard rocks in the canyon of the Uncompahgre above Ouray are polished and striated. Not only are the rocks at and near the bottom of the canyons glaciated, but high up on the sides. At the Black Diamond mine, 1500 ft. above the canyon bottom, the hard quartzite has been beautifully planed, grooved, and polished by the passage of the ice. An enormous amount of débris has been carried down from the Uncompahgre and its tributaries by the ice, and many hundred million tons of glacial detritus may be seen piled up in great moraines near the village of Ridgway, down the Uncompahgre river below Ouray.

Pack Train Crossing Snowslide, Canyon Creek.

Snowslide at Water Hole, Canyon Creek.

The San Juan mountains are famed for the num-

ber and size of the landslides that occur there. They range from small, inconsequential slips, some of them of recent date, to masses covering ten or more square miles, whole mountain sides having moved down to lower levels from some higher place. The most extensive of all those in the region is that on the north side of Gold hill, near Telluride, where rock covering a tract of fully ten square miles has slipped down. The landslides are of several kinds and include one peculiar type which appears to have occurred with marked frequency in this region. It has been designated 'rock-streams'. These are numerous and are found at the heads of the various glacial canyons in many of the high amphitheatres, or 'basins', as they are locally called. The United States Geological Survey recently issued, as Professional Paper No. 67, an interesting description of the several landslides of these mountains, under the title of 'Landslides of the San Juan Mountains, Colorado', by Ernest Howe, in which the various types of slides are classified and their origin discussed. This report contains many fine illustrations of landslides, talus slopes, and 'rock-streams'. Various origins have been assigned to the last. Mr. Howe considers the rock-streams to be the result of abrupt rock falls in which great masses of rock became suddenly detached from the nearly vertical cliffs above, and tumbling down, rushed forward from the base of the cliff, forming a long talus of relatively low-angle slope, being entirely unlike the ordinary talus usually found at the foot of cliffs. The slope angle of the latter generally approximates 35 degrees. Mr. Howe quotes Chamberlin and Salisbury* as follows:

"The loose débris on steep slopes sometimes assumes a sort of flowing motion and descends the slope with some such form, and at some such rate as a glacier."

Mr. Howe, commenting on this, says: "Although such explanations might hold true in the case of some of the smallest rock-streams, hardly to be distinguished from ordinary talus, in the writer's opinion they cannot account for the notable examples of rock-streams described in this paper."

I had an opportunity to see several of these unusual and interesting rock-streams, passing along the base of one and riding directly over the surface of two more, besides having an opportunity to view a number of others at a short distance in several of these basins. The streams were in Pierson and Silver basins, above the Atlas and Revenue mines, and in Savage and Marshall basins, near the Tomboy and Smuggler-Union mines above Telluride. In form they resemble glaciers, the corrugated surface, like a series of wrinkles approximately parallel with the advancing front of an ice mass, bearing a remarkable resemblance to crevasses. These I believe to be due to corresponding fissures in the ice formerly present beneath the rock débris. To me it seems that these rock-streams merely represent accumulations of rock fragments on the surface of the last remnants of the glaciers, which at one time occupied these elevated basins. So long as the ice rivers were in motion the rocks falling almost constantly upon them were carried away on their surfaces or embedded in the ice, and were in time deposited in the rock heaps which now form the lateral or terminal moraines in the neighboring canyons, or in the valleys below. When the glacier became so diminished in size because of changing climate that it no longer had sufficient volume to travel down the slope where it lay, the rock fragments falling from the cliffs began to accumulate upon its surface, and today as a result these so-called 'rock-streams' are found. In substantiation of this theory it is interesting to know that at the Tomboy mine in Marshall basin, near Telluride, a raise was driven on the vein which, reaching the solid rock surface, entered and passed through 60 ft. of ice and was then continued upward through a mass of loose rock débris, emerging into daylight on the surface of the rock-stream. There appears no reason to doubt that this mass of clear ice is all that remains of the great glacier that once filled Marshall basin, and the fact that the rock-stream completely covers the ice certainly suggests the correctness of the theory that all the rock-streams in the San Juan mountains owe their origin to a similar cause—that of rocks rolling down from the neighboring cliffs upon the remnants of the glaciers. One of the accompanying illustrations gives an excellent view of a rock-stream at the head of American basin, and is republished by permission of the United States Geological Survey.

On an elevated limestone plateau, several hundred feet above and south of the town of Ouray, is the noted Mineral Farm mine. It was idle at the time of my visit, but a great deal has been done on the property in past years, and open pits are numerous. There are also extensive underground workings reached through shaft and adits. A great deal of sulphide ore is still to be seen in the various workings, and it is not unlikely that when the cost of transportation and ore treatment is lower the property will be again successfully operated. A fault, striking in a northeast-southwest direction, passes through this hill, and it is possible that an extension of the ore-shoots occurring in the Mineral Farm mine may be found in the limestone to the southwest, toward Mt. Hayden. The Mineral Farm mine is equipped with a hoist and concentrating mill. Adjoining this property on the south is the Legal Tender group owned by the Legal Tender Exploration Mines Co., a local corporation, of which I. A. Martin is president, and Edwin J. Canavan is superintendent. In the belief that the ore-shoot of the Mineral Farm extends into the Legal Tender ground, preparations are under way to develop it, and at the time of my visit a shaft had been sunk 100 ft. through what appeared to be landslide material, though at the bottom the rock seemed to be in place and some good-looking ore had been found. A day or two before I visited the place the hoisting engine had been broken and the mine was idle awaiting the return of the piece sent away for repairs. Although the rock in the bottom of the Legal Tender shaft appeared to be in place, it was much shat-

* Geology, Vol. 1, 2nd edition, 1905, pp. 232-233.

tered and still suggested landslide phenomena. In fact, the whole hillside looked as though it was composed of the débris from above, the entire mass having slipped downward. However, when the shaft has reached a point as low as the bottom of Canyon creek it is likely the formation will be found in place. It is not at all improbable that in the Legal Tender, as in the Mineral Farm, ore may be found in undisturbed formations at a higher point to the southeastward of the fault previously mentioned.

An excellent road has been built up Canyon creek from Ouray to the mines near the head of the forks of the creek. These include the Camp Bird, Revenue, Atlas, San Pedro, Virginius, and a number of others less noted. All of the properties mentioned are on the high divide separating Ouray from San Miguel county, and just over the divide from those first mentioned are the Smuggler-Union, Liberty Bell, Tomboy, Japan-Flora, and a number of others. The total production of these mines has exceeded $124,000,000. The cost of road building in these extremely rugged and high mountains is excessive, but the record of the famous mines mentioned shows that the expenditure was fully justified. The road in many places has been blasted from the solid rock, which here and there overhangs the roadway, and in winter the dripping of the water, which freezes as it falls, builds up great icicles at the roadside which have to be broken down with hammers or blasted from time to time to keep them from forming and completely obstructing the passage of teams and pack-animals. There are several small mines between Ouray and the Camp Bird mill, which is situated near the forks of the canyon, six miles above Ouray. The most important of these is the Thistledown, which is equipped with a mill run by water-power. An aerial tramway connects the mine with the mill. The ore deposits here occur in a quartzite near the top of the sedimentary series, a bed of conglomerate which is the basal member of the Tertiary volcanics, lying a few feet above the mine workings. The Thistledown mine was said to be looking well and improving under development.

Canyon creek occupies the bottom of one of the wildest and most picturesque gorges in the San Juan mountains. The walls of the canyon rise to great height on either side, and in many places they are rent from base to summit by fissures, some of which contain ore. Open fissures are numerous. Some are merely great rents in the rocks; others, at one time filled with crushed rock, are now open, the fragmental material having been removed by decay and the wearing away by water, frost, and wind. The mountain-sides consist of a series of vertical cliffs rising one above another, separated by steep slopes which in some places are covered with rocks and soil; in others only bare rock is exposed. Pine, aspen, and a few other species of trees, with some underbrush, grow wherever they can find sufficient soil to support them as far up as timber-line. The altitude of this line varies somewhat, but is seldom lower than 11,000 ft. and not often over 11,500 ft. above the sea. It is surprising to see that in many places good-sized pine trees grow close up

Landslide or 'Rock-Stream' at Head of American Basin.
(After Howe, U. S. Geological Survey.)

to the line, whereas one would naturally expect them to diminish gradually in size approaching the limit of timber growth.

On these steep mountain-sides snowslides are of frequent occurrence in the spring when the warmth of the sun begins to thaw the winter's snow. Nearly every spring the slides take place and are often disastrous in their consequences. Mills have been destroyed, and many lives lost. Often avalanches can be anticipated and those in the vicinity seek a place of safety until the snow has rushed down into the canyon and the danger is over. At other times they come almost without warning and then all in their path are swept down to almost certain death. Last spring a snowslide came down the east side of Canyon creek about four miles above Ouray and caught a number of men and more than 20 pack-animals. The snow came from a height of more than 2000 ft. above the canyon bottom, gaining momentum with every foot of its fearful flight, plunging wildly into the bottom of the gorge over a vertical cliff several hundred feet in height. It filled the bottom of the canyon and rushed up on the opposite side, covering the roadway and overwhelming men and horses. Only one man escaped, I was told, by jumping quickly behind a boulder, where he was found and dug out by the rescue party. One of the accompanying illustrations shows a tunnel excavated through this snowslide for the passage of vehicles. It was later widened and the cover removed.

In hot-water heating-boilers the steam-gauge shows the height of water in the system in pounds pressure. Before starting up, go to the expansion-tank and see that the water is at the correct height in the tank. Then return to the boiler and make a mark with red paint on the steam-gauge where the needle stands. Use this mark as a guide in filling boiler when necessary. The needle should always stand at this mark when the boiler is in service. Some boilers are provided with altitude-gauges similar to steam-gauges; if provided, their correctness should be tested in the same manner as the steam-gauges by noting their readings when the water is at the correct height in the expansion-tank. In hot-water systems no valves should be allowed in the pipes leading to or from the boiler and heating system, except radiator-valves. If such valves are in, have them removed, for if the valves are inadvertently closed an explosion will occur. An explosion of a hot-water heating-boiler will also occur if it is not directly open to the atmosphere through the expansion tank; it is a duty of the person in charge to trace out the pipe-line from boiler to tank and to know that it is open and safe. No safety-valves are required on hot-water boilers open to the atmosphere through the expansion-tank. Insist on gauge-cocks and water-glass being provided for the boiler as a safeguard.

The water of many hot springs about the vents of volcanoes, whether directly in the crater or not, contains boric acid. Large deposits of colemanite are supposed to be the result of precipitation of calcium borate from springs of this kind.

PERUVIAN PLACER MINES

Important placer work has been undertaken by a company of English and French capitalists under the name of Aporoma Goldfields Limited, at Aporoma, province of Sandia, department of Puno, Peru. This company holds 129 pertenencias or 1277 acres of auriferous gravel, 155 miles from the station of Tirapata on the Southern Railway of Peru, itself distant 310 miles from the port of Mollendo. The Andes are crossed at the Aricoma pass at an elevation of 16,800 ft., and the mines are on a ridge of the eastern slope, 7000 ft. above sea-level. The zone is undoubtedly the bed of an ancient river which some geological disturbance has lifted far above its original level. The gold-bearing stratum lies above a bedrock of blue slate, and varies in depth from 50 to 400 ft., with a width of from 1500 to 1800 yards. The dense undergrowth that now covers it can easily be cleared by burning. The gold is finely divided, averaging something over 40c. per cubic yard of gravel, the gold being 0.935 fine.

The water supply for hydraulicking is mainly from the Cascada de Huayna, about two and a half miles from the upper workings and 200 ft. above them, 400 ft. at the lower end of the property. This source gives a minimum flow of 25 sec. ft. Two other supplies are available at considerable cost, but should not be needed. The disposal of tailing offers no difficulties, for the immediate side boundaries of the property are formed by the Huayna and Paechani rivers which run at least 1000 ft. below the bedrock and are capable of carrying away any quantity of tailing. Work has been begun on rebuilding the ancient trail from Limbani, which is so overgrown and so steep in places that some £9000 will have to be spent to allow the giants, conduit pipes, and electric-light plant to be taken in. From the railway to Limbani, the cart road of the Inca Rubber Co. will be used. G. Allen Crane of Merricks, Crane & Co., London, engineers for the company, who is general manager in Peru, is at the mine pushing forward the construction and states that well within 18 months extraction of gold will be under way. This is the first large undertaking of this nature in Peru, the only previous work being higher up in the mountains, nearer the Poto glacier, where the Poto hydraulic mines have been operated for several years by an Argentine syndicate whose manager is Mr. Ingolby. These are now producing gold at a good profit. The districts of Sandia and Carabaya have been well known for many years for their richness in placer gold, and it is hoped that the capital that is being brought into Peru for the purpose of exploiting this region will develop an important industry.—*Peru Today.*

Native antimony and stibnite (antimony sulphide) occur in at least two localities in California. One in San Emedio canyon, in northern Kern county, the other two miles southwest of the city of Corona, in Riverside county. There may be other places in California where the native metal occurs.

Origin of Gold 'Pockets' in Northern California

By Oscar H. Hershey

It has long been a question in my mind as to the exact rôle played by the 'secondary enrichment process' in the production of gold-quartz deposits. Many writers, when dealing with the subject, go elaborately into the effect of the process in concentrating the salts of such metals as copper and silver, but they seem to have exhausted their energies by the time the gold is reached, dismissing it with a few short paragraphs and scarcely any specific examples. This, with personal investigations in many gold-quartz districts, has led me to believe that the formation of workable gold ores by the secondary enrichment of the upper portion of the sulphide zone has been of relatively slight importance; but I believe the process has not been entirely inoperative in the concentration of gold, and I wish to ascribe to it, or rather to a modification of the process as usually understood, the origin of certain gold 'pocket' deposits of northern California.

When I first entered the western portion of Shasta and the eastern portion of Trinity county, about thirteen years ago, I made the acquaintance of a number of 'pocket hunters' who pointed out a certain contact as preëminently the 'pocket' horizon of the region. This contact is between the Clear Creek volcanic series and the overlying Bragdon slates. The volcanic series consists largely of altered andesites, traversed by rhyolitic bands and bound together by innumerable dikes into a great igneous complex which forms the visible basement rock in much of the country between the upper Sacramento and Trinity rivers. The Bragdon formation consists of several thousand feet of thin-bedded black slates alternating with thick-bedded blue-gray quartzites and conglomerates. It was laid down in a horizontal position on the surface of the volcanic series, but folding and faulting have made the contact very irregular, so that it varies as much as 600 to 1000 ft. in altitude on opposite sides of a narrow ridge. In the valley of the Trinity river, the contact line averages several hundred feet above the stream level between Trinity Center and Eastman Gulch, but in places rises to 700 or 1000 ft., and in others the black slates come down to the river level. Hence, the contact is generally tilted at various degrees up to vertical. At the contact the black rock frequently has a shining lustre and a schistose structure due to shearing. This gives it imperfectly the power of a gouge to deflect underground waters. The volcanic rock near the contact has generally been decomposed, softened, and changed to a dull brown color; it is popularly known as porphyry. In places there is a thin vein of quartz between the so-called porphyry and the black schistose material, but generally they are in actual contact or separated merely by a thin seam of ferruginous dirt. The dirt seam often carries a little free gold, but the pockets are said to be found near or where seams of quartz penetrate the porphyry downward from the contact. The gold lies in a thin, flat sheet upon the igneous rock and under the slate, and in some cases extends a short distance into the former formation, rarely into the latter. It is in the form of coarse and fine grains that have a peculiar smooth and rounded surface, quite unlike the free gold in quartz veins. An experienced California miner can readily distinguish an isolated particle of pocket gold from both placer and vein-quartz gold. There are rarely threads, but sometimes nuggets of considerable size are found. The miners say the gold has been melted and certainly in places it appears as though many of the grains had been partly liquefied and combined into large porous nuggets. I believe, however, that this is deceptive and that the deposits were formed in the presence of less heat than most gold deposits in bedrock.

In a paper on the 'Origin and Age of Certain Gold Pocket Deposits in Northern California', in the July, 1899, number of the *American Geologist* I advanced a theory in regard to the origin of these gold pockets, of which theory I then said I had a monopoly. So far as I know, I have continued in the enjoyment of this monopoly, but I now wish to repudiate the theory. I had recently returned from the Isthmus of Panama, where I had been impressed by the concentration of gold into hollows of the soft bedrock on a certain seashore, and I conceived the idea that these northern California pocket deposits had been concentrated by wave action into hollows of the surface of the igneous rock at the time the sea was advancing to lay down the Bragdon formation. The hypothesis was favored by the fact that there was an erosion interval between the deposition of the two formations. The Clear Creek volcanic series is older than certain Devonian limestones in the Kennett region, and the Bragdon formation is younger than these limestones. In short, the volcanic series was planed down by subaerial erosion before the sea advanced and deposited the Bragdon sediments on it. There is nothing impossible in the theory advanced eleven years ago, but now I have a better explanation, one which I think accords well with all the known facts. I came in time to realize that the pockets are nearly always found in the vicinity of mineralized shear-zones in the altered volcanic rock, that may have furnished the gold. In the *Mineral Wealth of Northern California* of January 15, 1901, in a paper entitled 'Pyritic Veins of Northern California', I described several groups of pyrite-impregnated shear-zones that occur in what I called the Clear Creek greenstone, the Abrams mica schist, the Trinity serpentine and the Salmon hornblende schist. I was too optimistic about the future of mining operations on these veins in general, for I was led into a misconception of their true gold content. In those days I placed too much confidence in the reliability of the average country assayer, and I was led astray by the assay certificates shown me by the owners of many of the "large low-grade base ledges." However, some gold is probably present in all of them, and ranges between a strong trace and $1 per ton.

For the purpose of this paper I wish to call particular attention only to the mineralized shear-zones in the Clear Creek volcanic series. They are found throughout its extent, but are best developed in certain limited districts where they are from 5 to 200 ft. wide, averaging between 20 and 30. They are usually quite regular in outline and traceable commonly from 1000 ft. to a mile. The outcrop has a schistose structure and is heavily stained with iron oxide resulting from the decomposition of pyrite. Below the zone of oxidation, the rock is a white or light greenish aggregate of quartz and sericite mainly, impregnated with small cubes of iron pyrite or in places containing irregular bunches of coarsely crystallized pyrite. The same system of base veins passes eastward into the copper-bearing veins of the Iron Mountain and Copper City districts, but in the Trinity Mountain region there is not much copper present.

Usually there is no free gold found in connection with these veins, not even in the oxidized portion or in the loose dirt below the outcrop, but careful assays show the presence of a small amount of gold and silver. This may run up to $2 or $3 per ton in places, but 50c. might be a fair estimate of the average gold content of the entire group. This gold is probably in an exceedingly finely divided condition. It was deposited by heated solutions that ascended along the shear-zones from great depths and partly replaced the schistose country-rock with sulphides.

I believe that some of this finely divided gold passes into solution in the zone of oxidation and is leached out by the descending meteoric waters. These waters make their way through small crevices and porous zones in the altered volcanic rock and slates until they escape into the streams. Much of the gold in solution probably is carried away by the streams, some may be deposited in cracks in the rock to form the so-called 'pocket seams' that have been such a prolific source of placer gold in the region between the Sacramento and Trinity rivers, and the remainder goes into the 'pockets'. The reason that the slate-volcanic rock contact is the great 'pocket' horizon is, that it is there that the gold-bearing solution first reaches a carbonaceous rock—the carbon precipitates the gold. The water may reach the contact by traveling nearly horizontally through inclined strata or by ascending under hydrostatic pressure. The sheared slate so frequently found along the contact aids in holding the solution to it while the gold is being deposited. Probably, also, water issuing from the slate carries the precipitating agent. For a long time the point of union between the precipitant and the gold-bearing water remains at one place at or near the contact and thousands of dollars' worth of gold is thrown down with a space of a few cubic yards or less. This certainly is secondary concentration by meteoric waters circulating near the surface, though it is not secondary enrichment in the sense ordinarily meant. I have supposed that the limonite found in the pockets has been derived by oxidation of pyrite which was deposited wtih the gold, but I am not certain. Pyrite has been deposited in northern California in comparatively shallow stream deposits and on the surface of glaciated serpentine boulders buried in till, so there would be nothing unusual about its deposition by meteoric waters in the gold pocket deposits. It is important to know whether the limonite has been deposited as such or has been produced by oxidation of pyrite. In the former case it would demonstrate that the gold pockets are strictly sub-surface phenomena, as they appear to be. Sometimes, when one is exhausted, a thin gold-bearing thread or seam leads to another, but they are never found far beneath the present surface. However, whether deposited in the zone of oxidation or just below it, I am pretty confident that the gold is derived from the mineralized shear-zones in the volcanic series and is transported in solution in ordinary cold meteoric waters circulating within several hundred feet of the surface of the earth.

Amalgamation in the Drum Lummon mill of the Montana Gold Mining Co. at Marysville, Montana, showed by a series of experiments that silver in the ore was amalgamated on the plate with difficulty. The finest, that is, highest-grade gold, was always recovered nearest the lip of the mortar, an increasingly greater percentage of silver being amalgamated as distance from the battery increased. Millmen usually clean up the entire surface of the plates, placing the amalgam all in a single pan or granite kettle, giving no attention to the varying grade of gold on different parts of the plate. A few experiments in this direction are advisable in any plate mill. They may lead to interesting and valuable results.

At the Kimberley and De Beers diamond mines in South Africa, the diamond-bearing earth when hoisted from the mines is trammed in trains of cars to a level field covering several square miles. There the 'blue' ground is spread out and exposed to sunshine and rain for a period of about four years, which permits the earth to disintegrate so that when it is put through the mills the separation of the diamonds will be as complete as possible. After crushing, the pulp is passed through concentrating machines and the concentrate run over inclined boards covered with a thick coating of grease. Strange as it may seem, only the diamonds adhere to the grease, all of the other stones of whatever kind passing over into the tailing.

THE MARCUS ELIPSOGRAPH

On the opposite page are working drawings for constructing an elipsograph designed by H. D. Hannah of the mining engineering corps of the Cananea Consolidated Copper Co., and published by his permission. The device is not patented and is offered freely to his fellow engineers by Mr. Hannah. It is based on the principle that one-fourth the difference of the two axes will describe a circle about the centre. A model was made at Cananea and proved satisfactory in practice. The machine is perhaps made sufficiently plain by the drawings. Fig. 3 is a detailed cross-section of the pieces shown in Fig. 2.

Compensation for Industrial Accidents

By David Ross

The American Mining Congress, at its late session at Los Angeles, California, adopted a resolution which clearly commits that body to the principle of legislation favoring definite compensation in the case of industrial accidents. This is a marked forward step and is the more significant when the fact is recalled that a large portion of the delegates represented employers of labor whose co-operation is essential to secure such reform in our present law and practice. It not only attests the humanitarianism of the men who have their capital invested in legitimate mining, but also reflects their business ability. The movement has become an organized effort to substitute for the unjustifiable waste that now marks every attempt to adjudicate accident claims, a plan, inexpensive and easy of enforcement, that will place the responsibility on the whole industry and yet will consider fairly and treat equitably every interest. It is unfair to the employers that they should be made the subject of interminable legal assaults in which designing lawyers play upon the gambling instincts of injured men. It is no less unfair to thrust upon the injured man or his dependent family the entire burden of the loss sustained through accidents, a great per cent of which is the result of trade hazard for which neither employer nor employee should be held liable. The purpose of the resolution adopted at the Los Angeles meeting is to save the money now squandered in useless litigation, and give it, under proper regulations, to those employees who may be injured, as compensation in part at least, for suffering and loss of earning power. The compensation thus provided is to be recognized as a proper liability of the business and to be charged against it like all other legitimate costs. The wonder is that the American people with all their indomitable energy and enterprise have not been the leaders in this, the most important conservation movement. Instead, any one of twenty-one foreign governments might be accepted as a model. The United States is the only civilized nation that persists, in this respect, in its adherence to an outgrown, obsolete legal policy.

The legislature of Montana, at its last session, enacted a law, effective December 1 this year, authorizing the levying of a tax of one cent per ton on all coal mined and sold in that State, for the purpose of providing a fund from which to compensate those injured in connection with the coal mining industry. The New York legislature, upon the recommendation of its Commission on Employers' Liability, enacted two laws effective September 1 this year, one optional and the other providing compensation for accidents occurring in certain non-competitive industries. The Illinois commission which was created by act of the special session, 1910, partly on account of the awful disaster at Cherry, reports to the governor, C. S. Deneen, under date of September 15, the results of six months' investigation of the subject. Unfortunately, the members were unable to agree upon a measure. While the employers on the commission were favorable to a compensation act, certain of the labor representatives, though not opposing the plan for compensation, felt that it should follow and not precede a comprehensive employers' liability law. Because of this division of opinion the commission adjourned without recommending any particular bill. The failure is regretted, but it does not relieve the legislature about to meet the responsibility of squarely meeting the issue; in fact, the dominant political party pledged its candidates for the legislature to do so. The valuable data collected by the commission and incorporated in its report will prove of great service in the task of formulating a law on the subject. Several other States, notably, Wisconsin, Minnesota, Michigan, and Massachusetts, have commissions now engaged in the work of proposing changes in present employers' liability laws, the reports of which will be submitted for consideration this winter. The conclusions or recommendations of such commissions necessarily depend upon legislative approval to become effective. If accepted, certain selfish interests will probably attack the measure in the courts, thus postponing indefinitely the time when they become effective. Anticipating the ultimate enactment of laws requiring compensation in all cases where employees are disabled, would it not be advisable for associations of employers in conjunction with their employees, to put into immediate operation by voluntary agreement a plan that would fully dispose of the legal contentions resulting from industrial accidents?

After a trial of more than half a century, the present system of litigation growing out of personal-injury claims, founded on statutory or the common-law theory of negligence, judged by its results, has failed. Whatever justification the principle may have had in the earlier and simpler stages of our industrial evolution, any further attempt to apply it to the complicated conditions of the present day must be attended with greatly increased embarrassment to the courts by taking up their time to the exclusion or delay of more legitimate business. In addition, there will be denial of simple justice to injured workmen or their dependants, and ever-increasing annoyance and expense to employers who in many instances are compelled in self-protection to contest the suits. Employers are familiar from experience with the defenses interposed against claims of this nature, so that it is unnecessary to discuss the rules of contributory negligence, assumed risk, the relation of fellow servant, and other doctrines proclaimed from time to time by the courts. They are also familiar with insurance organizations which in consideration of a fee, that is never earned or is dissipated in expenses that should never be incurred, agree to relieve them in part from the legal consequences of an accident for which an uninformed jury may hold them responsible. The situation created by our failure to give even-handed justice, has made it seemingly obligatory on the part of many

to seek protection in the nature of liability insurance. That, too, has miserably failed. This is true first, because the protection is incomplete; second, because real responsibility cannot be permanently and successfully transferred; third, because the injection of a foreign interest, usually without conscience and with no particular concern for the rights or interests of employees, intensifies friction and widens the gulf between employers and employees; and fourth, because the plan is organized for private or corporate profit, is maintained at great expense, and constitutes a severe tax upon the industry, only the smallest fraction of which finds its way into the homes of injured workmen. This plan, like the legal practice under which it has been developed, now stands condemned, and the task of the moment is the substitution of a system that will remove on the one hand the requirement for a suit in the civil courts, and on the other the necessity of depending for protection upon insurance companies as at present organized.

The only proposition to consider is that of substituting for the present expensive and wasteful plan, the policy of compensation under which the victims of industrial accidents would receive in the case of all injuries a definite sum equal under many existing laws, to one-half wages during incapacity, and for fatal accidents, in the case of the head of a family, the aggregate of three years' average earnings. There is nothing new or revolutionary in such a scheme. It has long been the settled policy of more than a score of foreign governments, some of them adopting it over a quarter of a century ago. The policy is based on the sound economic theory that the losses sustained by workmen from accidents received in the line of their employment form a legitimate tax upon the industry responsible for them, and that the earning power suspended or lost in consequence should, in part at least, be recouped out of the profits of the enterprise and charged against the business in the same manner as are breakages, depreciation of plants, and other unavoidable costs of production.

Mining operators may have been deterred from adopting a compensation plan under the impression that the vanishing margin which unlimited competition has left in the way of profits in many cases, makes it impossible. This conclusion may have been formed without fully considering the expense of present methods. A prominent manufacturer in Illinois, for his own information, recently checked up his casualty accounts for a period of nineteen months. Somewhat to his surprise, he discovered that the amount required to compensate all his employees who were injured during that time (on the basis of the English compensation law) comprised but one-fifth of the premiums he had paid for accident insurance during that time. The aggregate value of the total coal product of Illinois for 1909 was over $50,000,000; that for the entire country being $615,000,000. The addition of nine-tenths of 1% to the estimated sale price would be sufficient to allow the payment of one-half wages to every mine worker for time lost on account of injury and $2000 to the families of all those who were killed during that year, and yet competition is nowhere as keen in mining as in coal production. Because of certain laws, employers are not yet in a position to protect themselves against the inexcusable waste incident to our whole competitive system, but present restrictions need not prevent the inauguration of a policy in relation to accidents, such as that herein suggested, which, while the cost might be as great or greater than at present, would carry with it the comfort and satisfaction that whatever sums were paid out on such account, would go directly, and what is equally important, *immediately*, to those who are most entitled to receive them.

The practice and the law should unite with ethics in requiring that the financial loss caused by injury to a workman should not be imposed upon him alone, but shared as far as can be, by the society receiving benefits from his labor. Certain employers contend that to provide compensation for accidents would operate as a direct inducement to carelessness, and that instead of less there would be more casualties. Fortunately, such an opinion among employers is rare, and it is enough to say that the experience of foreign countries, working under compensation laws, shows without exception that the accident rate has been reduced. In the matter of industrial accidents the purely legal question as to where the personal responsibility rests should not be considered at all. It is not, strictly speaking, a personal affair for the reason that in extra-hazardous occupations, like that of railroading and construction work, coal and metal mining, accidents occur chiefly as a result of the inherent dangers of the calling, making it impossible in most cases to determine the question of negligence as defined by the law. Our difficulties in these respects are but multiplied in the foolish attempts to apply a legal theory that can have no logical or reasonable relation to the existing industrial situation or to our new social concepts of the real duties and responsibilities of men. A capable and distinguished judge, having a long and varied experience in the trial of personal injury suits, declares he could write in ten minutes a fair and comprehensive law on the subject of employers' liability. It should be a simple act comprising a few lines requiring evidence of the fact that an injury had been sustained by a workman while in the course of his employment, and the earning time lost on that account. These few words clearly define the basis upon which accident claims should be adjusted; the balance is merely detail. Eliminating the disturbing issue of negligence, there would be no longer a basis for quarreling over whether the employer be liable or not. The only question likely to give rise to a difference of opinion is in partial disability cases, in which the degree of injury has to be determined, and the time of the courts need not be occupied in such hearings, as those matters may be adjusted by commissions organized for that purpose.

Some confusion exists in the minds of workingmen regarding liability and compensation laws. This is shown in the attitude of certain labor lead-

ers who oppose all plans proposing compensation until a comprehensive employers' liability law is enacted. A law providing compensation for injuries is a distinct liability law without the uncertainties that inevitably attach themselves to any proceeding under a general liability act. Every statute attempting to define employers' liability is essentially based on the legal idea of negligence. Wholly aside from the particular defenses which the rulings of the courts allow, there can be be no recovery, under a general liability act, except on proof of negligence on the part of the employer. Under such a procedure, with any kind of a law, the burden of furnishing evidence in support of the charge of negligence, is upon the one seeking to recover damages. There can be no escape from this obligation on the plaintiff's part, and the record of litigated cases shows only too frequently how lamentable has been the failure to supply the needed evidence, and this, too, in cases where neither the doctrine of fellow-servant, contributory negligence, or assumption of risk had been pleaded or allowed in defense.

While in a few cases under the general law judgments have been recovered and sustained for considerable sums of money in damage suits, the amount of the judgment recovered in the average case is scarcely equal to the expense required to defend it. After a careful investigation, S. C. Kingsley, of the National Conference of Charities, discovered that in fifty contested cases, where the claimants were successful in dodging every legal technicality, the aggregate amount recovered was $8749, or an average of $174 for each. In the case of the Cherry disaster, the adjudication of the claims was founded on the English Compensation Act, and fifty families received an aggregate of $90,000, or an average of $1800 each. If the real concern is for the welfare of the families of injured workmen, surely there can be no reason for hesitation in the matter of a choice between the two systems. One offers a definite amount paid directly without the expense or intervention of agents or attorneys; the other presents the skeleton of a hope—the prospect only of a long-delayed lawsuit with the final result always uncertain.

The hoped-for millennium is still far off. Society is still forced to deal with men and situations as they are, not as wished, and in legal contests with rich and powerful interests the injured workman, represented by a contingent-fee lawyer, finds himself at a disadvantage when pitted against the trained corporation attorney. In no other way can the increasing number of verdicts for the defendant be explained. It is incredible to suppose that the workman who performs all the labor, assumes all the risks, and suffers all the pain will consent to a further continuance of an unequal contest.

The number of mining accidents in coal and metal mines is quite evenly distributed, those of a fatal character exceeding three in every thousand employees in each class of mines. Public attention, however, has been directed chiefly to accidents in coal mines on account of recent frightful disasters in some of which more than half a thousand lives have been lost at one time. The great loss of life in the mines of West Virginia, Ohio, Pennsylvania, Illinois, and Colorado within a period of two years, with a proportionate loss in our metal mines, although not so extensively advertised, imperatively demands that everything possible be done to diminish the number of accidents and to care for their victims in a humane and businesslike manner.

Every calamity brings in some form its compensation. These terrible experiences may have been required to arouse in men a true sense of their responsibility to their less fortunate fellows. The devastating floods that destroyed the city of Galveston ten years ago made necessary the commission form of government for cities, a system which, beginning with that wrecked municipality, is now spreading over the country and offers hope of escape from the blight of municipal corruption. If out of the wreck of industrial accidents, the result of inevitable dangers, there shall come reasonable laws recognizing in a broader way the rights and interests of all men, some recompense will have been made and the lives of our workers shall not have been offered in vain.

MINE DRAINAGE

In wet mines water occurring in the upper levels may be prevented from descending to the lower part of the mine by building low dams about the stations and conducting the water to a tank beneath the level. Sometimes, when water falls so abundantly in a vertical shaft as to make passage through it very disagreeable, this trouble may be averted to a great extent by clearing all débris from the plates, and tacking on to the edge next the compartment, thin strips of lath, or on top of the plates next to the edge, strips of molding one-half to three-quarter inch high. These extend entirely around the shaft, and are placed on as many sets of plates as necessary. The result is to turn the water to the back of the plate where it runs down on the lagging, almost entirely obviating the dripping water into the open compartment. At the several levels, dams may be constructed, as suggested above, to keep the water coming in above one level from descending to the next below. The water accumulating in the tanks beneath the levels may be removed by pumping or by bailing. If by the latter means, a pipe of liberal size is laid from near the bottom of the tank to the shaft, where is arranged a gate-valve and hose, the latter being fitted with an arrangement to hang the lower end on a hook, above the level of the valve and out of the way. When it is desired to load a skip, the skip is lowered to a point just below the valve, the valve is then opened and the water pours into the skip. When full, the skip tender shuts off the valve, hangs the hose on the hook, and rings the skip away, the operation being repeated until the tank is empty when the same thing is repeated at another drainage level.

Good extraction from ores can be expected only when both machinery and process are adapted to the ore under treatment.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Oil Land Legislation

The Editor:

Sir—In view of the action of the Mining Congress at Los Angeles in the matter of the location of oil placer claims, I have hoped that some of your eminent contributors would have given their views on the subject, for it is, to many mining men, a very important matter, and I should have much preferred that an abler pen than mine had brought up the subject. As I understand it, the status of an oil-placer location is just this, that anyone (a citizen) may make a location; but until oil is found, the locator has *absolutely no title* to the land. In other words, the location gives him practically no right whatever, for even if he is drilling, a second or third party may do the same thing on the same 20 acres, or 160 acres, as the case may be, and the first to strike oil can take the location regardless of the priority of location. This is, I am assured by excellent legal authority, the status of an oil-placer location; although the same authority stated that an intruder *might* be enjoined by law; also, that he, and others of the legal profession, doubted whether the courts would uphold such a ruling. This means that to make a location means a lawsuit. Again, I believe there is also a ruling, or resolution of Congress (I write under correction) to the effect that each of the associated eight locators (*bona fide*) of a 160-acre tract must develop his holdings. This ruling or resolution seems to me to have been made without due consideration, for while it is true that eight persons are the *minimum* that can locate 160 acres, there is no limit to the *maximum*. In the case of oil especially, the expense of well-boring is very great, and a greater number of persons can, and usually do, associate themselves together to bore for oil than would be the case in gold placers.

Let us suppose, for the sake of illustration, that 1000 persons associate themselves to acquire an oil claim and bore for oil, and that they agree to share the expense equally; also, that they either go in a body or send a committee of eight, to locate 160 acres of land, the name of each one appearing on the location notice. Now, the point is, that they —the 1000—are all *original locators*, and under the ruling *each* must develop his holding. As each one would have a one-thousandth part of 160 acres he would be entitled to $160 \div 1000 = 0.16$ of an acre, and as there are 43,560 sq. ft. in one square acre, each would have 6969.6 sq. ft.; as $\sqrt{6969.6} = 83.48$, each would have a piece of ground 83.48 ft. square. Now, it may be, and is, possible to drill a well on a piece of ground that size, if only one well is to be bored; but it is wellnigh impossible when 999 persons are doing the same thing at the same time on each 83.48 ft. square of ground; and if you increase the number to 2000 or 3000 associates, it becomes wholly impossible. No law or ruling can oblige a man to do the impossible.

The consensus of opinion at the Mining Congress was that fair laws should be enacted to protect the locator and give him a reasonable length of time in which to find oil. Is it not time that the men interested in mining and oil come to some definite agreement as to what is proper and fair to all; and then, knowing what they want, demand such legislation as is necessary? There can hardly be two opinions, one would think, as to the absolute fairness of giving the locator a reasonable length of time—say three years—in which to prove whether he has oil or not. It is such rulings as the above that are turning public opinion against conservation, for such methods of conservation, and the advocating of the lease system, tend to conserve the natural resources of the country for the moneyed power, for the rich can buy, and they can pay royalties.

I should like to see this question discussed in your columns, and hope that it may lead to united action by the mining fraternity. It is also a question of practical and intelligent legislation, and one in which mining men especially should take a leading part. It may be thought that I am straining the point by using 1000 persons as an illustration, but even that number is not unknown in adventures of various kinds, and I believe is not unknown in mining ventures. An association need not incorporate, and many a mining company has more than 1000 shareholders. However, my object is to show the state of chaos into which we have drifted, and to try to find a way out.

CHAS. R. GENT.

Trimmer, California, November 23.

A Cyanide Problem

The Editor:

Sir—A statement of the principles embodied in Designolli's process for treating gold ores containing antimony may assist in suggesting a solution to the 'Cyanide Problem'. Briefly, the process consists in crushing ore, or treating the ore with a solution of bichloride of mercury and sodium chloride, and for its basis rests upon the facts that when an acid solution of any salt of mercury is exposed to the action of an electric current the salt will be decomposed and metallic mercury deposited on the cathode, and when the cathode is gold, will result in amalgamation. When clean iron surfaces are in contact with a salt of mercury, in a weak acid solution, on touching them with gold the salt of mercury is decomposed, the metallic mercury thereupon amalgamating with the gold. And, that chlorine has a great affinity for antimony.

In operation, the antimony compound is decomposed, the antimony uniting with the chlorine, while the gold combines with the metallic mercury.

LEE FRASER.

Punta Arenas, Costa Rica, October 15.

Note: Commercial bichloride of mercury, or corrosive sublimate, costs 90c. to $1 per lb., and sodium chloride, or commercially, common salt, costs 2 to 4c. per pound.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

No patented mining claim in Nevada, nor any other State, is subject to re-location, no matter how long idle.

Straightway valves that leak may sometimes be repaired by turning the disc which forms the valve, presenting a new face to the valve seat.

Placer deposits may be prospected satisfactorily by means of a well-boring outfit. It requires experience, however, to secure reliable results by this method, as well as by any other.

Mercury fulminate is never used commercially as a blasting agent on account of its prohibitive price and the extreme danger incident to its handling. It is handled in small amounts, and then only with the greatest care.

A reinforced concrete standpipe 50 ft. diam., 106 ft. high from the inside of the bottom of the tank to the top of the cornice, and with a capacity of 1,500,000 gal. has been completed and is in service in the water works system of Attleboro, Massachusetts.

The maximum width for reverberatory furnaces has been determined by long experience, to do the best work, as 14 to 16 ft. The length may vary from 40 to 116 ft. Greater length than the latter has not been found to afford any additional capacity or economy.

Both Livingstone and Stanley tell of the natives of the Upper Congo and Arruwimmi rivers, in equatorial Africa, shooting lumps of rich copper ore from muskets. This ore has been found abundant in Congo Free State, particularly in the southern part, in the Katanga region.

The cost of shaft-sinking per foot varies greatly, according to size and shape of the opening, and with the character of the rock. The shaft sunk in soft ground is not always the least expensive, for soft wet ground often entails expense that is wholly unnecessary in hard-rock shafts.

A mineral deposit need not of necessity be a 'true fissure vein' to be either extensive or valuable. Some orebodies, the result of impregnation, are worth millions of dollars and are sufficiently extensive to satisfy the most exacting. The Homestake gold mines, the lead-silver deposits of the Coeur d'Alene, the Copper Queen and United Verde of Arizona, are types of ore deposits which are not fissure veins.

Gas engines have been found very useful and generally satisfactory in the southwest mining regions, but although this type of motive power is excellent, the engines require a man of experience to operate them. A novice sometimes fails to get good results from the best engines made and may ruin one in his bungling attempts to remedy a difficulty the nature of which he does not understand.

The largest single mass of solid gold ever discovered in California was taken many years ago from the Bonanza mine at Sonora, in Tuolumne county. It was worth $40,000 and was accompanied by very rich quartz worth all told $320,000 more, the entire pocket containing $360,000. This mine produced more than $2,000,000, the greater part of which was pounded out of the rock in hand mortars. In later years a 2-stamp mill was built on this noted and peculiar mine.

The rock dacite, so frequently referred to in the literature descriptive of the mines at Goldfield, Tonopah, and elsewhere in Nevada, is a quartz-bearing andesite. The rock is usually gray in color, sometimes red or buff colored, due to presence of iron oxide; is rough to the touch, but may be so thoroughly altered by percolating mineral solutions as to be difficult of identification. It may be thus rendered hard and dense by infiltration of silica, or soft and white by kaolinization of feldspars.

Sulphides of the mines of the Mother Lode of California vary greatly in value—from about $20 to $150 per ton, the average probably being about $40. Some of the fissure veins produce sulphides worth over $100 per ton, when in a rich ore-shoot. Large masses—zones of mineralization rather than fissures—usually carry lower grade sulphides. There are exceptions to this, however, for the Zeila mine at Jackson, Amador county, produces high-grade sulphides, though the ore contains relatively little free gold. At the Golden Gate mine, near Sonora, the gold was found almost wholly in the sulphide mineral, principally pyrite.

For making mine ladders none but good lumber should be selected. Make them with 12 in. between the sides and have the steps not over 8 in. apart. When the distance from the top of one step to the top of the next is more than 12 in. climbing becomes laborious. Men can climb much farther in safety when the ladders are of proper construction. Ladders should never be placed vertically in a shaft where it can be avoided. Give them a slope, with landings every 15 ft. If this be not practicable, place a plank at every 40 to 50 ft., at a sufficient distance from the ladder to permit men to pass readily, but where they may rest if necessary.

At hydraulic mines the streams of water are ordinarily used under a head varying from 150 to 300 ft. A much heavier pressure is extremely dangerous. Under all high pressures the nozzle or giant, as it is called, is securely anchored. A stream under 300 ft. head would instantly kill a man should he be so unfortunate as to be struck by the solid portion of it. Nozzles for hydraulicking vary in diameter from 2 to 10 in.—6 or 7 in. being the most common. These nozzles vary somewhat in form, the most of which variations are patented, the object of the several types being to prevent spraying of the stream.

Special Correspondence

PANAMA

Members of the American Institute of Mining Engineers Inspect the West Locks and Working Methods on the Canal.

The working day on the Isthmus is 8 hours, but it is divided into two parts, namely, from 7 to 11 in the morning and from 1 to 5 in the afternoon, thus avoiding the extreme midday heat. In order, therefore, to see the actual working operations, it is necessary to make an early start, and consequently the special train at the service of the Institute party left the station, a few hundred yards from the hotel, at 8 o'clock every morning. All of the remaining hours of the days spent in the Canal Zone were needed in order to carry out the program. The Isthmus of Panama has a reputation for rain during its rainy season, and on November 4, when a more than usual amount of tramping had to be done, it made a strenuous effort to maintain its reputation. While this somewhat added to the discomfort of the day, it was fortunate in that it gave better opportunity to observe how the work was kept going in spite of difficulties. In any other place work would be suspended; here the workmen simply wade in mud and water knee or waist deep, and pay no more attention to the rain than if it were so much perspiration. It has to be a flood to cause even a temporary suspension during working hours.

The first visit of the day was to the unfinished locks at Miraflores and Pedro Miguel, the steps by which the canal is elevated from tidewater at the Pacific end of the canal to the main channel. With wet clothes and muddy feet, the party walked through the locks and marveled at the bigness of the thing, the completeness of the organization, and the unexcelled character of the workmanship. Whatever one's opinion may be in regard to the wisdom of the building of the canal, no intelligent, unprejudiced observer will say that Uncle Sam's money is being wastefully expended in this the greatest engineering work ever projected. In every foot from Colon to Panama it reflects the genius and the power of the man in control, Colonel Goethals, a man modest and quick in manner, genial and good-fellow-like in disposition, strong in organization, in command in details, and in executive management.

After the inspection of the locks, the visitors were taken to the pumping station on the flats of the Rio Grande, and to the portion of the canal where California hydraulic mining methods are applied to the excavation work. Two giant nozzles wash down the easily disintegrated sediment and the mud is pumped through 16-in. pipes to a settling pond off the right-of-way. The method is cheap and expeditious. The morning trip was completed by a visit to the electric-power plant where is developed the energy used in the operation of the hoists and other machinery employed in the construction of the locks. This plant will be permanent, as from it will be taken the power to operate the locks and the electric locomotives to be used to tow vessels into and through the locks. No steamer will be allowed to pass the locks under its own power. The afternoon was occupied by a trip in tugs to the Pacific entrance of the canal. Here excellent opportunity was given to observe two distinct methods of subaqueous excavation. One dredge fitted with air-drill apparatus is boring holes in the submerged rock which is then broken up by dynamite. The other is fitted with a Lobrietz rock-breaker, consisting of a solid steel shaft about 50 ft. in length and weighing 10 tons, which is raised 15 or 20 ft. and allowed to drop of its own weight on the rock. It operates through a well in the centre of the dredge. Exact figures as to the relative cost of excavation by the two methods are not at present available, but it is hoped that by the time the work is completed reliable comparisons may be made. On the way back from the water trip the party stopped at the quarry on the side of Ancon hill where rock is being quarried and broken for making the concrete used in the construction of the locks. The rock is rhyolite, and better material for the purpose could hardly be secured. The quarrying and crushing of the rock are conducted on a large scale, in keeping with other work on the canal, the side of the hill being taken down in steps about 40 ft. high, and by the time the canal is completed a pretty large piece of Ancon hill will have been taken away. No dimension stone is obtained or desired, and the quarrying operations are accordingly not difficult, being simply drilling, blasting, and loading. The rock is hauled in trains to the breaker on the side of the hill below the quarry where a car at a time is dumped directly into a Gates crusher, from which it passes to four jaw-crushers, thence by gravity to revolving screens, and thence to the railroad cars.

The first session of the Institute in the Canal Zone, and the fifth of the meeting, was held in the evening in the social room of the Tivoli hotel at Ancon. The first speaker of the evening was Colonel Gorgas, chief of the sanitary department, who gave an interesting account of the fight against the yellow fever mosquito, the attacks of dysentery, and the threatened invasion of the plague which had broken out at La Boca, one of the island resorts on the bay and the place where the French engineers had built their hospital. No greater victory over disease has ever been accomplished than that won by Dr. Gorgas and his staff. Dysentery has practically disappeared, the plague got no lodgment, and there has been no yellow fever on the Isthmus in three years. It is one of the most healthful spots on the globe, and, as here eternal vigilance is the price of health, no let-up is allowed in the exercise of precautionary and preventive measures. The stream beds are kept free of flow-retarding weeds and grasses, crude petroleum is kept automatically fed upon the ponds and pools, and disinfectants are being constantly applied to every spot where disease germs may propagate.

C. W. Hayes, of the U. S. Geological Survey, who arrived unexpectedly from Washington at noon this day, for the purpose of making some geological studies of the Isthmus from the exposures made by the excavations, gave a brief account of the general geologic structure of the region, though, he explained, as he had only been on the Isthmus 14 hours, he had not been able to make any detailed study. The session closed with a description by Gardiner F. Williams, with lantern-slide illustrations, of diamond mining at Kimberly and gold mining on the Rand.

Saturday was excursion day without business. The excursion was to the island and old, very old, settlement of La Boca, and was made on tugs furnished by the Commission. The weather fortunately was ideal and the day highly enjoyable. Many took advantage of the excellent beach, a few hundred yards from the hospital building, for taking a dip in the waters of the Pacific. All were glad of the 'respite and nepenihe' from the sight-seeing tours, particularly as the evening was to be spent in dancing, this diversion having been arranged by the management for the younger members of the party and for the members of the Tivoli Club, the social organization among the officers and officials of the Canal Zone citizens. November 6, being Sunday, was also a day of rest, but the majority of the tourists accepted the invitation extended to visit the hospital to see how the sick and injured were cared for. In the evening a session of the Institute was held in the social room of the hotel. Edward W. Parker, of the U. S. Geological Survey, presented an abstract, illustrated by lantern slides, of his paper on 'Recent Developments in the Undercutting of Coal by Machinery.' The paper in full was printed in pamphlet form, and distributed to those present. It has also been published in the November Bulletin. Mr. Parker was followed by David B. Rushmore, who showed some interesting lantern-slide views of electrical machinery and of the application of electricity to mining and other industries and to domestic use in heating, lighting, and cooking. Gardiner F. Williams closed the session with some beautiful and entertaining views of South African scenery and of the big game so plentiful in that part of the globe. All day of Monday, November 7, was

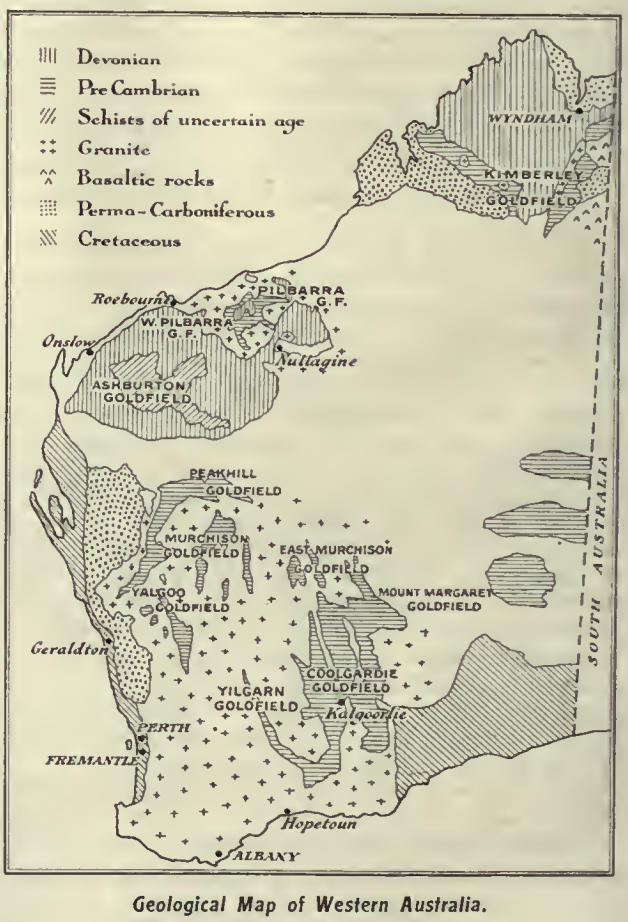
given up to a visit to the dam and locks at Gatun on the Atlantic side of the Isthmus. The usual good fortune that has marked the entire trip continued, for while there were numerous heavy showers, they almost without exception occurred while the party was under cover, and rain ceased while the inspection of the work of dam and lock construction was being made. This was one of the most, if not the most interesting and enlightening days of the meeting, and was a fitting culmination, for it left a profound and lasting impression upon each of the party. The work at Gatun is the keystone of the whole great enterprise. Every fair-minded, intelligent American citizen who visits the Zone must as a result of his visit be prouder of his citizenship and of the men doing the work. The evening was spent in preparation for an early start the next morning for Colon and the beginning of the homeward journey. At 8 o'clock Tuesday morning the special train which had been at the service of the party during the week of its stay left Panama for Colon, and promptly on schedule time the *Prinz August Wilhelm* cast off.

The seventh session of the meeting was held Wednesday afternoon in the dining saloon. It was devoted to a discussion of the Panama Canal, each speaker being allowed five minutes to give expression to the features that had impressed him most. The unanimity of opinion was remarkable. There was not a dissenting voice to the general feeling that if the Canal is to be built the present type is the one dictated by existing conditions. Equally unanimous was the feeling that the men in charge of the work were the men for the job, and eloquent tributes were paid Col. Goethals, Col. Gorgas, and their associates. It was recognized that but for the work of sanitation carried on by Col. Gorgas and his aids, the American enterprise would have suffered the same adversities and have come to the same disastrous end as did the French. The feeling of security against disease has had an important part in making effective the 'ginger' with which by example, more than by precept, Col. Goethals inoculates the entire force.

LONDON

Russian Copper Mine.—New Mine in Western Australia.— Copper in the Argentine.

Attention has been drawn in London recently to the operations of copper companies in various parts of the world, and it may be of interest to note the doings of some of them. I will start with the Spassky of Siberia, which after five years' hard struggle has now declared a dividend. This company was formed in 1904 to acquire the Spassky smelter, the Yuspenssky copper mine, and the Karagandy coal mines in the Akmolinsk district, Siberia. Reports were made by E. T. McCarthy and by Pellew-Harvey & Fell, and E. Nelson Fell was the first manager. He was succeeded by H. C. Woolmer two years ago. When additional capital was required in 1909, 50,000 new shares were guaranteed by L. Ehrlich & Co. and the Consolidated Gold Fields of South Africa. The copper deposit is notable for the richness of the veins. It has been difficult to set operations going in the past, owing chiefly to the distance of the copper mine, smelter, and coal mine from each other and from the Siberian railroad system. To give an idea of recent improvements, I may mention that in August 1909 the cost of copper production was £41 per ton. Since then the average has been only £29 per ton. At the Yuspenssky mine the main shaft has been sunk to 490 ft. and development at the 420 and 490-ft. levels are highly satisfactory. No decision has yet been arrived at as to the best method of treating the great quantities of lower-grade silicious ore in the mine. The amount of ore raised from the mine during May of this year was 2254 tons averaging 18% copper. Last month the first dividend was declared, at the rate of 12½%. Mr. Woolmer has recently done some prospecting on other parts of the company's extensive property, and this feature of the work will be gradually extended, for it is recognized that the surrounding country is highly mineralized and should repay exploration. The directors have also decided that the time has come when the company might use its established reputation in Russia for the furtherance of other mining schemes within the empire.——A new and promising copper mine has recently been opened up in the northern part of West Australia. This is the Whim Well, and it is in the West Pilbarra district, near the coast, east of Roeburne. H. R. Sleeman is general manager. During 1909, 6826 tons of ore was shipped averaging 15.3% copper, with a gross value of £65,273, and the net profit was £15,804. Out of this £20,729 was distributed as dividend, being at the rate of 15%. Since then the capital has been increased from £150,000 to £200,000, to provide funds for further development and for the installation of plant. The ore deposit is found in a flat lode which has been proved 3000 ft. along the outcrop, and for 2000 ft. it carries profitable ore. In the upper parts the ore is oxidized, and below, both by driving and by diamond-drilling, the deposit has been proved to contain sulphides high in sulphur and iron which will make a suitable smelting mixture with the oxide and carbonate. At the present time the best ore is picked and shipped to



Geological Map of Western Australia.

Europe in sailing vessels. Before deciding on the method of metallurgical treatment, full investigations are being made as to the characteristics of the various kinds and qualities of the ore, and further development will be made to prove the extent of the orebody. Another property belonging to the same company is a few miles distant, and is called the Mons Cupri. It is the intention of the directors to form a separate company to develop and finance this property. Taking it all round, the Whim Well company appears to have an encouraging future before it.—— The Famatina copper mine in the Argentine Republic near the Chile border has had, so far, an unfortunate history, but better times seem now to be at hand. The company, called the Famatina Development Corporation, was formed at the beginning of 1903. The progress has been slow, owing to successive managers either miscalculating the content and nature of the ore, or being incapacitated by the high altitude, 14,000 feet. The metallurgists who have reported on the method of treatment, among them T. C. Cloud, have been handicapped by want of knowledge of the resources of the mine. The directors have had much anxiety in connection with the financing of the company.

and from time to time issues have been made of various kinds of shares, participating bonds, and debentures. The financial results for 1909 were disastrous, as a debit balance of £51,163 was left. The smelter was re-started March 1909, but results showed that pyrite-smelting was not satisfactory, so heap-roasting was adopted on trial. As the results in the blast-furnace with roasted ore have been satisfactory it was decided to order a mechanical roaster. In addition another converter has been ordered. Hooper & Speak were appointed consulting engineers in July 1909, and S. J. Speak went to the mine in December. Subsequently Hooper, Speak & Fielding were made general managers, and they appointed A. W. Jenks manager of the smelter, and J. C. Vivian was made superintendent of the mine. The report on ore reserves by the late manager, Mr. Powers, was not accepted by the consulting engineers, because it was found that much rock and low-grade ore had to be mined in addition to the best quality ore, and they re-estimated the reserve at the Upulungos workings at 119,300 tons averaging 2.79% copper, 10¼ dwt. gold, and 9.3 oz. silver, and at the San Pedro 60,800 tons averaging 7.3% copper, 4 dwt. gold, and 1½ oz. silver. With the recently improved method of smelting and the correctly estimated resources of ore, the company will in all probability be able to report profits in the near future.

NOME, ALASKA

Sluicing Stopped Early.—Output $3,500,000.—New Dredges.

The sluicing season for 1910 is rapidly drawing to a close as these notes are written late in October. All sluicing operations which depended upon the ditches for a water supply were closed on the first or second of this month, as a rapid fall in the temperature at that time formed slush ice in great quantities and made it necessary to close all intakes and open waste gates to hurriedly empty the ditches throughout the district. The cold snap broke again on October 5, and the weather conditions were favorable for sluicing until October 18, but the ditch proprietors anticipating freezing weather from day to day, were afraid to reopen their ditch systems. In the meantime many small operators, taking water either through short ditches or pipe or hose-lines, directly from the creeks upon which their claims are situated, and those using small pumping plants where the water is circulated from a dam or lake, continued to operate through another three weeks under conditions as favorable as any part of the season. All dredge operations were continued without hindrance from the short cold snap, and three of them, whose managers will stay in the district this winter, are still running at this date. Sixteen others have been closed and their running season shortened by many days on account of the early closing of navigation this season, and the desire of managers and other officials connected with their operations to catch the last boat for the outside. The output for this season has been curtailed by at least a quarter of a million dollars by the steamship companies arranging their last sailings so long before the weather conditions would have compelled the dredges to close. The production from Seward Peninsula for this season, as shown by the Customs Office on October 20, is $3,467,608, as compared with $4,070,290 for last year. There will probably be $100,000 more added to this by the dredges still running, and from other sources which had not been reported at the Customs Office on the date mentioned. The falling away of a half million in the output this year as compared with last is due in part to the exhaustion of certain well known pay-streaks and in part to an unusually late spring. The early part of the season was cold and wet, and last winter's frost held a grip on the creek and river beds some three weeks later than usual. Many of the dredges were hindered in their operations, and although this loss of time has been offset in some measure by a late fall, for the reasons already stated, the large operators have not been benefited by it. I will venture the prediction that this season's output is the smallest that will be credited to Seward Peninsula for a great many years. Ten new dredges have been built on the Peninsula this season, each having a capacity from 1200 to 2000 cu. yd. per day. Two others are now under construction, and at least five new ones will be shipped in next season. This will make a total of twenty-four dredges, twenty of which will be prepared to begin operations as soon as the frost will permit them to start in the spring.

TORONTO, CANADA

Activity at Porcupine. — Cobalt Prospects Brighter. — Lack of Transportation Retards Development.

Porcupine has of late been the great centre of attraction in mining affairs, and a rush is anticipated as soon as the winter roads are in condition for traffic. Though snow has fallen in the district there has not been sufficient frost as yet to give a firm foundation for the sleighing. In the meantime considerable quantities of machinery and camp supplies of all sorts are being shipped to Kelso on the Temiskaming & Northern Ontario railway to await the opportunity for transportation to the camp. There is every prospect of an active winter, as many properties have been sold recently at high figures to owners who are anxious to begin development without delay. Rapid progress is being made with the electric railway which will connect Porcupine with the railroad, but as construction work can not be carried on except at a great disadvantage during the cold weather it is hardly likely to be available before next season. The six Herlehy-McPharland claims on lot 5, concessions 2 and 3, Tisdale township, about midway between

Cobalt, Ontario.

the Rea, or Connell Veteran, property and the Dome, have been sold by E. V. Perkins to a New York syndicate. Seven veins have been found on this property, one of which is 8 ft. wide and displays free gold. A large force will be put to work at once. The Temiskaming & Hudson Bay Mining Co., of Cobalt, has entered the Porcupine field and purchased the six Foster-Ellis claims in the northern part of Shaw township. Sinking will be started at once. The Consolidated Gold Fields of South Africa has lost no time in getting to work on the Rea property, and camp buildings are ready for a larger force. One shaft is down 36 ft., with a good showing of free gold all the way. A heavy winter's work has been mapped out. The Foster is awaiting supplies to start work on the sinking of two shafts, each 100 ft. deep, and 350 ft. from each other, to be connected by a drift. It has now a 30-ft. shaft on a wide quartz vein yielding free gold to that depth. The Dome has ordered a 40-stamp mill and will treat ore by double amalgamation, re-grinding, and cyaniding. The Timmins, which has a large body of ore blocked out, has contracted for a 30-stamp mill. The Bremner Veteran claim, comprising 160 acres, lot 9, concession 2, of Whitney township, has been purchased by a London banking firm identified with South African interests. It will be operated by a company chartered under the name of the Bremner-Porcupine Gold Mines Ltd. Charles Taylor, president of the Porcupine Gold Syndicating Co., of New York, a prominent Nevada operator, has bought the Freeland location adjoining one of the Armstrong-McGibbon groups. An English syndicate has taken over from A. S. Stewart the Carson-Hennessey-

Walker properties recently bought by him.——The position of some of the leading mines of Cobalt has considerably improved by reason of recent discoveries, especially at the La Rose, the value of the new vein on the main property being estimated at $2,500,000. At the Kerr Lake several veins of high-grade ore, running from 4 to 6 in. wide, have been cut in exploring the territory underlying the Lake. They are supposed to be continuations of the Crown Reserve veins. The Temiskaming & Hudson Bay, in driving at the 150-ft. level toward the Trethewey property, has struck a new vein from 2 to 4 in. wide., yielding 3000 oz. ore. The Wetlauffer is working in good ore below the 250-ft. level. A winze put down 22 ft. shows ore all the way down and a 6-in. vein at the bottom running about 300 oz. per ton. The Temiskaming has issued a highly satisfactory statement covering the nine months ended October 31, showing profits for that period of $597,364. It is taking out good ore at the 500-ft. level, though its best showing, so far, has been made at a depth of 400 ft. On the 175-ft. level of the Provincial an orebody 210 ft. long has been opened. The company will put in a small reduction plant. One of the largest shipments of bullion sent out by one mine left Cobalt this week, consisting of 44,125 oz. of silver bars consigned to London by the Crown Reserve.——The transportation difficulty is still hampering operations in the Elk Lake and Gowganda silver areas and mining is quiet. The Bartlett is being actively worked and is taking good ore from an open-cut and also driving on the 110-ft. level on a calcite vein. The Mann-Ryan of Gowganda is down 110 ft. and has struck a vein carrying good silver content in driving on the 85-ft. level. It has stored about $2500 worth of ore. The Montreal River Transportation Co., organized to serve the Elk Lake and Gowganda camp, has failed, owing to competition and lack of business.

ST. PETERSBURG, RUSSIA

Projected Russian Platinum Monopoly. — Perilous Prospects for the Platinum Trust.

The long-threatened direct intervention of the Russian Government in the platinum business is now definitely and formally announced as about to take place. The announcement states that the Minister of Trade and Industry has prepared a project of law, the effect of which will be to bring the entire platinum industry of Russia (and this, of course, means to within something under 5% of the entire platinum industry of the world) under the control of such a public body as may be constituted *ad hoc* by the Government with the approval of the Russian Duma. The project will be submitted to the Duma within a very short time. The story of Russian platinum is in some respects hard to understand, when one considers that the Russian Government has always been strong enough to have its own way in its own country when it so desired. The platinum deposits, as far as is known, are concentrated in the Urals and for a long time were exploited by one or two families who acquired very expensive habits and spent a large portion of their time enjoying life in Paris. The natural result was that as their tastes became more difficult to satisfy and more money was wanted, the platinum mines failed to supply the necessary means. Then the Western European financiers came on the scene and by a series of, shall we say, cleverly framed contracts got almost complete control of the situation in Russia. Then the monopolists, not content with the fine position they had attained, sought to make it stronger, and began a policy of market manipulation with practically no disguise in order to ruin the Russian producers and bring every element in the industry under their control. Finally the producers rebelled, held congresses, and appealed to the Government with such insistence as to compel the calling of an official conference to study what could be done to save Russia's practically only exclusive industry for the Russian people. After many drastic proposals had been considered, it is probably the most extreme project that has been adopted by the Government. To judge by the articles of the proposed law, it would appear as though the Government had decided to ride rough-shod over all the contracts that have been made with English and French houses respecting the supply and treatment of platinum. The chief articles run as follows:

1. To forbid the export abroad of unrefined (crude) platinum and to establish a period within which such prohibition shall take effect; always taking into account the time that will be necessary to enable the Russian official committee to erect a factory to treat all the Russian platinum. 2. To authorize the Minister of Trade and Industry to construct a platinum-smelting laboratory out of funds to be provided by the treasury, presuming that private enterprise shall prove unequal to the task of establishing such a laboratory. 3. To institute the issue of loans—by the Imperial Bank—on platinum, on the easiest possible terms for the producers, resembling the present system of loans on gold slime, and also to make loans to platinum producers in order to supply them with working expenses and further to encourage the provision of small credits to these firms; the regulations for governing the issue of these loans to be drawn up and executed by the council of the Imperial Bank. 4. To fix special rules for the sale, purchase, and storage of crude platinum, and also to simplify the control of the production and circulation of platinum. 5. That in the event of the law being passed containing the provisions of the first four heads, the necessary penalties shall be fixed to ensure their observance by all interested parties in Russia.

This proposition comes before the public at what might be called the psychological moment. The price of platinum today is higher than it ever was before, and perhaps it is just this period that is chosen, because the proposed law is more likely to find a favorable reception on the ground that a valuable industry will be kept for the country. It was at a similar period, some years ago, that the Russians woke up to the fact that, as they call it, foreigners were simply taking Russian wealth out of the soil and paying very little for it. It was then that one of the large mine owners took advantage of the failure of the French monopolist company to observe one of the clauses of the contract, to void it. Strenuous efforts were made to reconstitute the contract; but the Russians, thinking they had the ball at their feet, declined to be accommodating. The next step taken by the foreigner was to run the market down, which was done with such effect as to bring the Russian platinum industry into a state of ruin. It was when the producers had reached this unhappy position that they made their persistent and effective appeal to the Government which has had the effect described above. There can be little doubt that, matters having gone so far, the law will go through. But in event of the project becoming law, it is likely that serious international trouble may arise similar to what is threatened between Germany and the United States at the present moment. It is known, for example, that the enactment of the new German potash law on the top of contracts previously made between German potash mine owners and American contractors has set the two governments by the ears. Should, as appears almost certain, the new Russian Government project become law, the Russian Government will find itself in identically the same position toward the European monopolists as the German Government finds itself toward the American contractors for the output of the Aschersleben and other potash mines in the German Empire. Contracts exist which bind the largest Russian platinum owners to furnish the European monopolistic combine with their total output for many years, on terms which, unfortunately for the Russians, are particularly favorable to the Anglo-Franco-German combination. What the Russian Government will do to conciliate these live monopolists, with good binding contracts in their hands, in face of the position to be assumed by the new Russian platinum governing committee, cannot well be imagined. It is by no means likely that the outsiders will forego the advantages of their contracts. Perhaps a way will be found by enabling the European monopolists to come in under the protection of the new law and erect a factory in Russia for refining all Russian

platinum. This the French company had already offered to do before the project took shape. Should this be the way out of what will obviously be a most delicate situation, it is hard to see how the Russian producer is going to benefit. As far as he is concerned it will simply mean that he will be bossed from St. Petersburg instead of Paris.

NEW YORK

Activity of Postal Officials.—Market Conditions Unsatisfactory.—Talk of Copper Merger.—Calumet & Hecla.—Comment on Mines.

Activity by the postal authorities has been evidenced the past week by the raiding of some of the fraudulent concerns which have been vending alleged mining and oil stocks. A plan to reorganize the Ely Central and collect 25 cents per share in the process was halted by the postoffice department as fraudulent. A large number of illegitimate concerns which grew up during or since the Nevada mining boom have been halted effectively, for the first time.——The market situation generally is still unsatisfactory. The political victory of the forces allied against Mr. Roosevelt, for whose defeat Wall Street was avowedly working, does not seem to have brought any part of the public into the market-place. There are many articles written daily reviewing the fluctuations of the shares traded in on the New York Stock Exchange, but the one thought, outspoken, and between the lines, is that the public refuses to speculate or even to invest. It is this situation which is partly responsible for the anxiety of the financial leaders to put together a copper merger. During the past four or five years trading in mining shares grew beyond all previous experience in this country, culminating in the activity of the Nevada stocks in the boom days of Goldfield. Familiarity with mining stocks, the losses incurred in many precious metal companies, and alleged safety and long life of the copper mining, led many from general mining shares into copper. A new leader, a new public to come into the market with it, is needed and a copper merger seems to be the most available material.——A year ago copper merger talk was heard everywhere; now it is being revived more strongly than at any time since Mr. Morgan went to Washington to obtain official sanction for the project and failed to get it. As might be expected, predictions are various. The different combinations mentioned include about all of the possible groups. There is no doubt that the step will be taken.——A 42-point rise in Calumet & Hecla is said to be due to the knowledge that the leader of the Lake region is now willing to become a part of a great consolidation, and by way of preparation is to form a holding company to take over the shares of the subsidiary corporations now in Calumet & Hecla treasury.

Butte, Montana, is receiving as much attention as though it were a new mining camp. The settlement of the North Butte-Tuolumne trouble and the buying of the latter for the account of the former; the making of the Butte-Ballaklava, the tremendous development of the East Butte; the opening of a rich orebody by the Butte Coalition; the difficulties of the Butte & Superior, all attract interest. North Butte has always been a public favorite, and anything which improves its position is welcomed.——The joint meeting of the Calumet & Arizona and the Superior & Pittsburgh boards has been adjourned to December 5, when it will be held in Chicago. Dividend action has also been deferred until that time.——One of the features of the mining situation is the extensive development of the various porphyries—the Ray Consolidated, Chino, Miami, and others. As part of the equipment for the Ray Consolidated and the Chino, D. C. Jackling recently purchased 58 automatic stokers, costing $60,000, of the Automatic Stoker Co. The significance of the transaction lies in the amount involved in supplying a minor part of equipment.——The holders of Greene Consolidated Copper have taken a new turn in their attempt to force an accounting from the Greene-Cananea organizers. Two holders, alleging that there is to be a new Cole-Ryan syndicate organized to control the copper output and the metal market of the United States and Mexico, have filed a suit asking that any exchange of Greene-Cananea for the shares of such new corporation be enjoined, and also asking for a receiver for the old Greene Consolidated. There is some evidence that the various Cole-Ryan properties are to be gathered together, but at present it is certain that nothing more than a preliminary merger is contemplated.——The ore shipments for the past week from Cobalt showed a marked increase. Unless there is a decided slump in output, the current year will furnish another high record for the camp. With increased milling facilities, and higher prices for silver, Cobalt is earning greater net profits for its stockholders than ever before.——George Wingfield is to discuss the mining situation in Nevada at a banquet to be tendered to him in New York on December 30 by leading Nevada operators. There are many holders of cheaper Goldfield stocks who will be greatly interested in what the president of the Goldfield Consolidated will have to say, especially if he touch on the probable developments outside of the big company.——It is announced that the Montana-Tonopah will become a dividend payer, distributing 5% before Christmas.

SALT LAKE, UTAH

Denial by D. C. Jackling.—Montana-Bingham. — Centennial-Eureka. —News of Other Properties.

D. C. Jackling, general manager for the Utah Copper Co., has denied the much-published report that he is to accept the management of all of the Western interests of the Guggenheims.——The Montana-Bingham Co., successor to the Bingham-Butte, has driven its main tunnel through a 100-ft. body of milling ore. Samples of the ore recently assayed from 1.7 to 3% copper, with streaks or high-grade ore. A lower adit is being driven to cut this vein at depth. The Montana-Bingham is in good territory, being situated on the Quinn fissure which cuts through the Boston Con., Utah Copper, Starless, and others, and is considered the main copper-bearing fissure in Bingham.——Hugh MacDonald, superintendent of the Silver King Consolidated of Park City, has resigned his position on account of ill health and has been succeeded by James Mara.——The Little Bell Con., one of the properties opened by Mr. MacDonald, is just trying out its new mill. The plant has a capacity of 100 tons, which, with the shipping ore exposed in the mine, is expected to continue the dividends recently paid by the company.——The Centennial-Eureka has declared its second $3 dividend of this year, making a total of $27 per share since its purchase by the United States Smelting, Refining & Mining Co. in 1905. As there are 100,000 shares outstanding, this makes $2,700,000, to which should be added $2,917,000 paid before the property was sold.——The Iron Blossom has broken into a large cave similar to the one found in the Colorado which was productive of so much rich ore. The find was made on the 400-ft. level in the No. 3 workings. The cave is about 400 ft. long, north and south, and 60 ft. wide in some places.——The Lehi-Tintic Co. is planning to drive an 800-ft. adit which will tap the vein at a depth of 400 ft., and will cross-cut a considerable amount of promising territory.——The statement is made that work on the Jordan Valley railroad, to connect Alta with Jordan valley, will be commenced at once. Such a road would mean much to Alta district, but there is serious question as to its feasibility. It must follow a narrow canyon in which snowslides are common and in which the snow lies deep for five or six months of the year.——At the first session of the annual meeting of the Hornsilver Mining Co., T. Elliott Hodgkin was chosen director in place of A. I. Harrison, who died during the past year. Meantime some of the directors will visit the property so that a final decision on the building of a concentrating mill may be reached at this meeting.——A consolidation of the Baby McKee and Park City M. & P. Co. interests as the Howell Mining Co., has been effected. The property is in the south fork of Big Cottonwood canyon and not far from that of the Columbus Consolidated. The Baby McKee has been an important producer.

MEXICO

A Smelting Plant for Mazatlan. — Pacific Smelting & Mining Co. — Coal Production of Coahuila.—Montezuma Copper Co. — Cananea.—Matehuala Smelter.—Veta Grande.

Recent rumors of plans for the erection of a custom smelter at Mazatlan by the Guggenheim interests have been set at rest by the purchase of the concession for a custom plant there by the Pacific Smelting & Mining Co., the New York concern owning the smelters at Fundición and Guaymas, Sonora. The concession was granted by the Sinaloa government several years ago to A. H. McKay, then president of the Mercantile Banking Co. of Mexico City, and at that time closely identified with Southern Pacific interests in Mexico. The time limits for the beginning of construction and the blowing in of the smelter were extended some time ago, and the concession, which provides for important tax exemptions, continues effective. It is claimed the smelter will be built, and that western Durango, Tepic, and Jalisco, as well as Sinaloa, will contribute to it. Several months ago engineers, said to represent Standard Oil capital, visited mining districts of Sinaloa and Durango to investigate conditions as to the Mazatlan smelter project, and recently rumors of a 'trust' smelter at the Sinaloa port have been current. The Pacific Smelting & Mining Co. is not connected with the American Smelting & Refining Co., and with smelters at Guaymas, Fundición, and Mazatlan, it expects to have an important part in custom smelting in Mexico. Excellent progress has been made in securing contracts for copper and lead ores for the Fundición and Guaymas plants, and it is expected that both smelters will be in operation early in the coming year.——The growing importance of the coal and coke industry of the State of Coahuila is shown by a report covering production during the first nine months of this year, which gives a total of 1,213,163 tons of coal, and 165,653 tons of coke. The Mexican Coal & Coke Co., also operating the properties of the Coahuila Coal Co. and the Fuente Coal Co., is the largest producer of coal in that State, the output for the 9 months reaching 474,804 tons, with 36,029 tons of coke. The Compañia Carbonifera de Agujita ranked first in the production of coke, with a total of 83,575 tons, and produced also 168,584 tons of coal. A merger of this company and the Compañia Carbonifera de Lampacitos was effected some time ago, and the production of the latter, 19,373 tons of coke and 86,593 tons of coal, makes a total for the merged interests of 102,948 tons of coke and 255,177 tons of coal. The only other Coahuila concern producing coke is the New Sabinas Co., Ltd., which had an output in the 9 months of 71,623 tons of coal and 26,676 tons of coke. The production of the other coal concerns of the State was as follows: Compañia Carbonifera de Sabina, 210,837 tons; Compañia C. del Norte, 74,044; Compañia C. de Ciudad Porfirio Diaz, 59,269; Compañia C. de Rio Escondido, 63,609; Compañia C. El Fenix, 3791. The National Railways of Mexico (government merger system) some time ago granted a freight differential in favor of Coahuila coal and coke as against the imported products, and this has resulted in benefit to the Coahuila operators. ——The 1910 output of the Moctezuma Copper Co., operating the big Pilares mine of the Phelps-Dodge interests at Nacozari, in Sonora, will fall short of that of last year. Scarcity of water at the end of the long dry season resulted in the closing down of one unit of the 2000-ton concentrator, and the plant was operated at half capacity for some time. Last year the concentrator treated 510,094 tons of ore, producing 110,725 tons of concentrate containing 13,059 tons of copper. The net earnings were $1,104,454. It is estimated that the ore handled this year will not exceed 450,000 tons. Two aerial tramways built to carry tailing to storage grounds some distance from the river bed, where they are now deposited, will be in operation before the end of the year.——Bins to receive Miami concentrate are being built by the Cananea Consolidated Copper Co. Deliveries of Miami Copper Co. concentrate at Cananea are expected to start about January 1. The Cananea Consolidated has contracted for California fuel oil, which will be used instead of the Texas product. The present consumption is about 800 bbl. per day, and with the new reverberatory in operation and the central power plant completed the amount will be increased.——The Sonora Copper Smelting Co., which is building a 100-ton smelter at the Cobre Grande camp, three miles east of Noria, under a State concession granting exclusive tax exemptions in the Magdalena district of Sonora for 20 years, has ordered an aerial tramway to convey ore from the mine to the plant, a distance of 3500 ft.——The American Smelters Securities Co. is building an additional 500-ton furnace at its Matehuala smelting plant in the State of San Luis Potosi. This plant was purchased by the Guggenheim company early in the year from the National Metallurgical Co. The new furnace will give Matehuala a capacity of 800 tons per day. The Guggenheims previously owned the Dolores mine in Matehuala camp, and several other mining properties were acquired when they purchased the smelter.——The Veta Grande mine at Zacatecas, a famous antigua, is under option to English interests, but its purchase is by no means certain. The dump at the Veta Grande is probably the largest now in Mexico; it has been picked over repeatedly, and the average value is low. Veta Grande was formerly worked by the Anglo-Mexican Mining Co. of London. It is now owned by Mexicans.

BUTTE, MONTANA

November Output of Three Smelters. — Copper Production of Butte Mines for November.

The November copper production by the Washoe smelter at Anaconda, the Boston & Montana smelter at Great Falls, and the East Butte smelter, at Butte, aggregated 23,636,550 pounds. This is the quantity of the metal the Anaconda and associated companies plan to produce under the copper producers' agreement for curtailment. When some of the mines, by reason of the high grade of ore that is shipped, run over their allotment, the output of ore is cut down. For instance, the Butte Coalition mines are now shipping only about half the tonnage that was sent out before the curtailment agreement, its ore having for some time averaged higher in copper. The estimated tonnage of ore smelted, from the mines of the different companies, and the production of blister copper therefrom, for the month of November were as follows:

Companies.	Tons of Ore.	Lb. of Copper.
Boston & Montana ...	90,000	6,300,000
Anaconda	121,500	7,411,500
Butte & Boston	12,900	799,800
Washoe	12,150	741,150
Parrot	6,000	360,000
Trenton	12,300	762,600
North Butte	31,500	1,953,000
Butte Coalition	30,000	2,100,000
Original	21,000	1,302,000
Tuolumne	9,000	900,000
East Butte	9,150	1,006,500
	355,500	23,636,550

According to the best information obtainable, the Butte & Superior company is recovering from its financial reverses and when certain obligations come due early in the year the money will be forthcoming. When the Butte & Superior company took over the Butte-Milwaukee, it obligated itself to do certain development in addition to meeting certain indebtedness. The money to be paid is due in March next, and development is proceeding according to agreement. It was stipulated that the Butte & Superior should cross-cut through into the Butte-Milwaukee and this is being done. It is expected that an official announcement will be made soon that the bond issue has been taken care of, and that the proceeds, together with the earnings of the company, will give all the financial aid required to place the company in a good position. The company is now earning at the rate of about $30,000 per month, and it is believed this rate will be maintained.

General Mining News

ALASKA

The following was paid in San Francisco on November 28, 1910: The Alaska Treadwell Gold M. Co. dividend No. 91 of $1 per share; Alaska Mexican Gold M. Co. dividend No. 61 of 30c. per share; Alaska United Gold M. Co. dividend No. 15 of 30c. per share.——Under direction of the Alaska Road Commission, a trail is being made from Nome to Iditarod, and from Iditarod to Seward and Coquina. W. P. Richardson, at the head of the Commission, states that the entire trail will be brushed out by February 1. Sites for road-houses are being designated, and the trail will be finished next summer.

ARIZONA

COCHISE COUNTY

The Copper Queen smelting plant, at Douglas, with nine furnaces in blast, produced 8,800,000 lb. of copper in October. Besides ores received from the Copper Queen mines and those of allied interests, a good tonnage of custom ore is received, one of the Bisbee customers being the Shattuck. At this plant is smelted the concentrate turned out at the mill of the Moctezuma Copper Co. at Nacozari, Sonora. An additional brick stack, 300 ft. high, 14 ft. diam., is to be built to serve the reverberatory furnaces and roasters.——On the property of the Tombstone Con. M. Co. an important find of ore was made on the 800-ft. level, which is considered a continuation of the West Side lode. The west drift on the 1000-ft. level has been advanced 260 ft., and cross-cutting along the contact is being pushed. The normal pumping record is 6,800,000 gal. per day.—— The new crushing and cyanide leaching plant of the Commonwealth M. & M. Co., at Pearce, is finished and in operation, treating 125 tons per day. The new plant replaces one that was destroyed by fire several months ago.

GILA COUNTY

(Special Correspondence.)—The total amount of underground work accomplished by the Inspiration Copper company is 30,000 ft., and the churn-drill work during the past year and a half aggregates 40,000 ft. Three churn-drills are in operation on the highest part of the property. The force underground does about 550 ft. of driving and raising each week. T. R. Drummond, manager, is employing 160 men.——The Arizona Commercial Copper Co. has a new diamond-drill with which it is prospecting below the seventh level. The seventh hole was abandoned on account of a bit having been lost. The eighth hole will be put down 456 ft. north of the Eureka shaft and will tap the Black Hawk vein at a depth of 870 ft. The Eureka shaft is about 940 ft. deep, the tenth level in it will be established 1010 ft. from the surface, to correspond with the tenth level of the Superior & Boston mine, soon to be established. In this way proper ventilation for the workings of both mines will be provided.——The winze being sunk on the Old Dominion vein by the Arizona-Michigan Mining Co. has attained a depth of 155 ft. below the 500-ft. level, the bottom of which is in quartzite.——At the Superior & Boston mine, a drift on the eighth level has opened ore 150 ft. farther east than the orebody on the sixth level. In the face of the drift the ore ranges from 1½ to 3 ft. in width, and while the assays are not uniform some of them run 6.6% copper, the ore being oxidized.——The Barney Copper Co., organized several months ago by John D. Coplen of Globe, has purchased a Star churn-drill from the Cactus Copper Co. for use on Barney property adjoining the Live Oak holdings.——The Boston-Miami Copper Co. has moved its camp to the part of its property nearest the Live Oak, and has two churn-drills, with one of which a hole is being sunk on the Montezuma group of claims which was recently purchased.

Globe, November 26.

YAVAPAI COUNTY

The Venezia mine and mill are in operation in Crook canyon. The mill has 10 stamps, and amalgamating plates, the ore containing free gold. The mine is being further developed, and a steady production is anticipated.——A shipment of 30 tons of ore from the Curran & Norris mine, on Lynx creek, to the Poland mill ran $50 per ton.

YUMA COUNTY

Josiah Winchester and his two partners have developed a mine and built a 10-stamp mill near Vicksburg. It is said they have 100,000 tons of ore accessible in the mine and on the dump, the principal metal of value being gold, although there is a little copper. The mill is reported ready to be operated. The ore runs $8 to $12 per ton.

CALIFORNIA

AMADOR COUNTY

It has been decided to sink a 2000-ft. shaft on the Hardenburg mine, situated near Middle Bar. The South Eureka stockholders have financed the enterprise and J. J. McSorley, of San Andreas, has charge of the work. A hoisting engine, formerly in use at the Gwin mine, has been installed at the Hardenburg. The property was developed by a shaft 1000 ft. on the vein, sunk nearly twenty years ago by Hayward, Lane, and others.

CALAVERAS COUNTY

In the suit of James V. Coleman against the Lightner M. Co., the Third District Court of Appeals denied the application of the latter for a writ of prohibition to restrain the Superior Court of Calaveras county from proceeding with the trial. The title to a valuable piece of mining property is involved, and the company sought to delay trial of the case until the U. S. Land Office finally decided as to the issuance of a patent for the land in dispute.——A gold dredge is being built near Mokelumne hill to handle the hydraulic tailing on Chili gulch, the depth of which varies between 10 and 100 ft.——The Calaveras Copper Co. has acquired the Union copper mine, the holdings of which cover a mile on the strike of the copper zone.

INYO COUNTY

The Skidoo Mines Co., for the month of October, milled 1440 tons of ore, recovering $13,577.15 in bullion and producing concentrate estimated at $175; total, $13,752.15. Operating costs, $7833.93; development, $705.50; net profit for the month, $5212.72.

SIERRA COUNTY

Sol. Camp and associates, who have a bond on the Amethyst of the South Fork M. Co. at Forest, have opened a 4-ft. vein of ore containing free gold and arsenical pyrite.——A carload of ore shipped last week from the Red Star mine at Alleghany is said to have had a gross value of $5000. There is 6 ft. of ore in the vein.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Work was resumed this week on the Bellevue-Hudson mine, on Columbia mountain. It is proposed to sink the shaft 200 ft., and levels will be extended southwest from each 100-ft. station. Shipments of ore will be commenced at once.——Alkire & Co., leasing on the Seven-Thirty mine, have shipped some ore running 300 oz. in silver. Stoping in progress has exposed a streak of mineral from 8 to 12 in. wide.——Frazer & Co., working through the Hercules adit, have encountered an 8-in. streak of ore on the Seven-Thirty vein that mills from 425 to 450 oz. silver per ton.——The Amy property on Leavenworth mountain has been taken under bond and lease by W. S. McGintie and work will be commenced. There is exposed in the adit a streak of ore 18 in. wide, assaying 1 oz. gold and 14 oz. silver per ton.——Gava & Co., leasing on the fourth level of the Smuggler mine on Brown mountain, are making regular shipments of ore, settlement for which shows $400 net per ton.——A new house is being constructed at the property of the Accord M. & M. Co., on Saxon mountain. Within the next two weeks machine-drills will again be brought into use and the adit will be driven 600 ft. farther to intersect the series of veins on the property.——The Alco M. & M. Co. is driving an adit, expecting to intersect a vein in a few days.——Another con-

tract will shortly be awarded to drive the Prudential adit 100 ft. It is now in 869 ft. F. A. Maxwell is manager.——A small streak of ore has been uncovered in the breast of the adit being driven on the McKinley vein. Tests show from $75 to $80 per ton in gold and silver.

Georgetown, November 22.

EAGLE COUNTY

The Killingsworth property of 8 claims, in Horn Silver mountains, near Red Cliff, has been partly developed by Elizabeth K. Brown, who has a vein of manganese ore 16 ft. wide, within which is a 2-in. streak of bismuth, 2 ft. of graphite, and a streak of black sulphide ore carrying gold and silver. The bismuth ore is said to run high in that metal. Further development is in progress.

LAKE COUNTY

Mining conditions at Leadville are steadily improving. This is being brought about by the increasing production of zinc carbonate, the opening of good orebodies in mines which were thought to have been worked out, and the advance in the price of silver. A number of new shafts are being sunk and work has been resumed in several old properties which had been idle. There is marked activity on Fryer, Rock, Carbonate, and Breece hills, and at the head of Big Evans gulch.——Ore shipments are regularly made from the Stevens shaft, on which Thomas Smith and associates have a lease. The ore is taken from an 8-ft. vein, 4 ft. of which samples 60% lead. In another part of the mine zinc carbonate ore is being obtained. The mine is on

Mineral Districts of Colorado.

Rock hill.——Zinc carbonate has been discovered by lessees at the Little Giant, on Carbonate hill. The body of ore opened has a strike south.——The Bertha, on Breece hill, since having been unwatered, is being further developed by lessees, who contemplate sinking the shaft 100 ft. deeper, to enable them to get at the different ore-shoots on their dip. The other mines in this vicinity which are operating consist of the Penn, Ballard, Curran, Grand Prix, Galesburg, Big Six, Highland Mary, and Black Prince, all of which are shipping ore.——The Nevada claim, east of the Little Johnny, on Breece hill, is under lease to Thomas Simpson and associates, who in the last two months have unwatered the shaft, put it in order, and cleaned out the levels. Pay-ore, consisting of lead sulphide, with silver and gold, was found 60 ft. below the surface, some of which is being shipped to the smelter. Smithsonite has been found in this mine, but the tonnage obtainable is small.——The Forest City, on Carbonate, under lease to W. A. Young, is producing iron ore which is being shipped. A body of lead ore, containing silver, has been discovered.

SAN JUAN COUNTY

The Ledge Con. M. Co., operating near Silverton, is concentrating 100 tons of ore and producing one car of concentrate daily. The sixth station has been cut in the shaft, and from it a cross-cut is being driven to the orebody which was opened and mined on the fifth, fourth, and third levels. ——The Iowa-Tiger Leasing Co., operating the Iowa and Tiger mines in Silver Lake basin, is shipping ore to the smelter and receiving encouraging returns. Development to open the shoot of ore at a lower level is in progress.——Among the other mines operating in the vicinity of Silverton are the Hercules, Gold King, and Sunnyside. The Gold Prince, after a run of five months this year, has closed down. It is a property which has been equipped at great expense.——The Intersection was operated successfully by the owners a part of the season, and was then leased to local men.——The Highland Mary, in Cunningham gulch, which operated during the summer and autumn, has closed down for the winter.——The Vermillion mill has been closed for the winter, but work in the mine is to continue, the plan being to have an ore supply by spring that will keep the mill operating next summer.——The Frank Hough mine, on Engineer mountain, will be further developed this winter. The final shipment of the year was made last week.

IDAHO

ADA COUNTY

(Special Correspondence.)—The Geo. F. Roth M. Co. has erected a 10-stamp mill which began operating on November 17. The plant has one classifier, two Wilfley tables, tube-mill, Portland filter, and cyanide leaching tanks. The concentrate is pulverized in the tube-mill and then cyanided. The plant was designed and built by F. M. Field. The property is in the Neal district.

Boise, November 26.

IDAHO COUNTY

The South Fork mine of the Elk City Mines Corporation, situated near Elk City, recently produced $2500 in gold bullion, which was recovered on amalgamating plates in the company's mill. The ore from which the gold was extracted was taken from a 6-ft. vein. J. T. Omo and associates of Spokane are in control of the mine.

LEMHI COUNTY

The Red Bird mine, 14 miles from Salmon, is developed by 2500 ft. of work, which opens on several levels a quartz vein between porphyry and slate; the ore is said to carry free gold assaying $5 per ton. It is stated that a large tonnage of ore is exposed in the stopes.——The Pittsburg-Idaho mine at Gilmore is said to be shipping daily 50 tons of ore.

SHOSHONE COUNTY

The Caledonia M. Co., for which Charles McKinnis of Wallace is manager, shipped silver-lead ore valued at $200,000 during August, September, and October. A raise in ore was made from the 500 to the 300-ft. level, and it is estimated that 50% of the ore between those levels is of shipping grade. In driving from No. 5 adit a body of shipping ore has been opened a length of 150 ft., with the face of the drift still in ore. The first-grade ore is accompanied by a big tonnage of ore of milling grade.

MICHIGAN

The Seneca, controlled and financed by the Calumet & Hecla, has the cropping of the Kearsarge lode for 1400 ft. between the Gratiot and Ojibway; also the underlie of the Kearsarge below the entire Gratiot property, and below parts of the Mohawk and Ahmeek. Satisfactory copper ore has been developed on the Kearsarge lode on the 920-ft. level. The drifts being advanced are carried 9 ft. wide instead of 6 ft. The shaft is in the foot-wall of the lode, and a number of cross-cuts have been driven to the vein. ——The United States Smelting, Refining & Mining Co. has an option on the Clark property in Keweenaw county, on which it has been exploring for several months with diamond-drills. The property is said to extend three miles south from Copper Harbor.

MONTANA

BROADWATER COUNTY

The Keating Gold M. Co., operating in Radersburg district, has sunk its new shaft to a depth of 600 ft., and is hoisting ore from the 500-ft. station. Driving on the 400-ft. level has reached a point 1000 ft. north from the shaft, all of which was in ore. This, with 1200 ft. of driving on the vein south of the shaft, opens the vein 2200 ft. on its strike at the 400-ft. level. In October 40 cars of ore were shipped to a Butte smelter, the returns showing an average of $19 per ton. The November shipments were between 50 and 60 cars. R. Hightower is mine superintendent.

DEER LODGE COUNTY

(Special Correspondence.)—The French Gulch M. Co. has 22 lode and 6 placer claims on French gulch, 21 miles south of Anaconda. Placer mining, which began here in 1865, has continued with little interruption since that date. In the last ten years quartz claims have been located at the heads of the ravines, and several veins and fissures of ore opened by shafts and adits. The country rock is granite, cutting through which are alternating dikes of basalt, porphyry, and aplite, having a north-south course. The three principal veins of the group strike east-west, and consist of fissures in granite, dipping 70° south. There are several porphyry intrusions into the veins, and these are considered the sources of mineralization. The croppings of these veins are defined and readily traceable. Development on one vein consists of several adits, one of which is 900 ft. long, and a 3-compartment vertical shaft, 200 ft. deep, from the bottom of which there is 850 ft. of driving on the veins. A raise of 135 ft. on the vein from this level connects with a surface adit. Development on the other two veins aggregates over 2000 ft. According to J. E. Beveridge, of Salt Lake, the ore occurs as sulphide and oxide, carrying gold, silver, and lead, with less than 1% copper, about 20% iron, and 20 to 27% silica. In the course of development 140 tons of ore was shipped which sampled $15 per ton, the greatest value being in gold. The property is equipped with ample buildings, hoisting engines, air-compressors, and steam-pumps. The company's placer holdings are said to include 200 acres of virgin ground. It is claimed that 15 acres of this was tested by sinking numerous pits to bedrock, the result showing 55c. per cubic yard. There is a good deal of placer mining equipment on the property, including an Evans hydraulic elevator, 1000 ft. of sluice-boxes, and 1300 ft. of 6, 8, and 16-in. iron pipe.

Anaconda, November 22.

LEWIS AND CLARK COUNTY

The construction of the plant of the Northwestern Metals Co. is in progress at Helena. These works are designed to treat the complex refractory ores of that part of the State. A. W. Burwell and C. C. Titus are active in the company as metallurgists.

NEVADA

ELKO COUNTY

Contact district, situated in the northern part of the county, 50 miles north of Wells, and 30 miles east of Jarbidge, has deposits of copper ore in limestone, veins on the contact of limestone and granite, deposits of copper carbonate a short distance from the contact, and low-grade chalcopyrite in limestone 200 ft. from the main contact. Exploration work by the United States Smelting, Refining & Mining Co. has been carried on during the past year. Development has progressed to some extent on a number of properties. The nearest railroad station is Rogerson, Idaho.

LINCOLN COUNTY

The Centennial-Pioche Co. has struck ore and a strong flow of water at a depth of 510 ft., and is installing a new 50-hp. hoist, cage, and pumping plant. The ore found at this depth is in limestone.

NYE COUNTY

(Special Correspondence.)—The Canyon mill, situated on the outskirts of Manhattan, is owned by the Manhattan Milling & Leasing Co., for which S. W. Steffner is manager. The plant, originally equipped with a Huntington mill, plates, tables, and cyanide tanks, now has in addition to these a Bryan mill, and by fine grinding the recovery by amalgamation is raised so high that cyanidation may not be necessary. Experience in this camp has proved that a high saving of gold is possible by adopting fine grinding and careful plate work. The ore received at the mill runs $18 to $20 per ton, and it is estimated that a saving of 92% can be made. The ore passes to a crusher, thence through a 6-ft. Huntington to silver-covered copper plates, having four drops. The tailing passes to a cone sizer, from which the oversize is elevated to the 6-ft. Bryan mill. The slime from the classifier joins the slime from the Bryan mill at the head of another amalgamating plate, the tailing from the latter going to waste. The machinery is now operated by electric power, and the mill capacity is being increased from 24 to 40 tons per day.——The War Eagle mill treated 400 tons of ore taken from the dump of the Big Four mine, the recovery of gold and silver therefrom amounting to $40,000. This ore belonged to Steen, Poak, and Chapman, of the Big Four Leasing Company.

Manhattan, November 25.

The Tonopah-Belmont Development Co., for October, milled 6546 tons of ore, and shipped to smelters 1135 tons. The precious metals extracted from both classes of ore consisted of 2492 oz. gold and 249,491 oz. silver, the gross value being $215,056. The net profits for the month are given at $102,469.

WHITE PINE COUNTY

The Amalgamated Nevada Mines Co., operating at Blackhorse, has put in operation its new 10-stamp mill. The company is said to have 1500 tons of ore ready for the mill that will assay $30 per ton. Part of this is is taken from the company's San Pedro claim, on which are an 800-ft. shaft, and a 160-ft. incline.——It is announced that the Ohana M. Co. has decided to erect a mill, the machinery for which has been ordered. Blackhorse is in the vicinity of Osceola.

UTAH

JUAB COUNTY

An important find of ore was made in the Uncle Sam mine, in Tintic district, by driving westerly on the level below the main adit. The vein thus opened strikes northwest, with a dip east. The new orebody is being developed by raises from the lower level; thus far it has a width of 5 ft.——The new shaft of the Eagle & Bluebell mine has been timbered to the 1000-ft. station, and ore-hoisting has commenced. The new shaft facilitates mining operations, and establishes better ventilation in the mine.——Two drifts are being run in the Mammoth mine; one of these is from the 1300-ft. level, the other from the 2100. The purpose of the latter is to develop an ore-shoot which was opened on the 1900-ft. level.

SALT LAKE COUNTY

Concentrating tables and other equipment are being installed for the third and fourth units of the mill of the Ohio Copper Co. Each of the four units has the capacity of 625 tons of ore per day.——The Utah-Apex mine, situated on Carr fork, Bingham district, has been developed during the year ended September 1, by 1545 ft. of driving, and 379 ft. of raises; stations cut amounted to 20,767 cu. ft. Important in the year's work was the finding of fissures and bedded veins on the fourth level in the western part of the property. No. 7 level, now in 500 ft., is expected to result in opening similar orebodies. The lead ore opened and available is estimated by E. P. Jennings at 111,500 tons. For eight months ended August 31, 1910, the amount received for ore sold was $311,583; mining costs, $202,388; development, $28,177; net profit, $81,017. As reported in last week's issue, no milling ore is to be mined for several months, during which period the mill is to be overhauled and the mine development pushed with vigor.——The new mill of the Utah Leasing Co. is finished and in operation. It has a crusher, rolls, and concentrating machinery. This company has a lease on the Old Telegraph mine of the

United States Smelting, Refining & Mining Co. The Last Chance mine of the Nevada-Utah company, situated in Bingham district, is under lease to Morris P. Kirk, who intends to mine on his own account, and will let several sub-leases. The property is well developed to a depth of 900 ft. The ore contains lead, silver, and gold.

SUMMIT COUNTY

The larger ore shippers of Park City district are the Daly-Judge, Silver King, Daly West, American Flag, and Little Bell. All of these, except the American Flag, operate concentrating mills and ship the greater proportion of their output in the form of concentrate. In this may be included the lessees at the Ontario, who are mining and shipping 50 tons per day of high-grade ore.

NEW MEXICO

DONA ANA COUNTY

Paul B. Davis, who has been developing the Philadelphia group of claims situated in the Organ mountains, recently shipped a lot of ore to the smelter at El Paso to be tested. According to assays the ore runs high in silver and lead. The properties are out from Las Cruces.

SOCORRO COUNTY

(Special Correspondence.)—The management of the Socorro mine has decided to develop in all parts of the mine and block out ore sufficient to justify doubling the capacity of the mill. This company has thus far followed a conservative policy, proceeding more cautiously than its immense holdings would seem to warrant. It owns a vast acreage of unproved ground surrounding the Fannie-Consolidated veins and over 7000 linear feet on these two lodes, less than one-tenth of which has been explored on the lower levels. Drifts have been advanced both east and west on the 600-ft. level, over 500 ft. of which was in the orebody cut several months ago. In a number of places it has a width of 25 ft., while in other places the walls have not been reached. It is a well-defined contact vein. The daily average samples taken from a raise being driven to the fifth level have assayed about $25 per ton. Air-drills are being operated in the various headings and the three-compartment vertical shaft will be sunk to the seventh and eighth levels, where it is expected to intersect the vein on its dip. Regular shipments of bullion and concentrate are being made.——The concentrating plant of the Ernestine M. Co. last week crushed 668 tons of ore, from which was produced 58 sacks of high-grade concentrate, in addition to the precipitate from the zinc boxes. The ore encountered several weeks ago in the eleventh level west, continues to hold its width and high grade.——The oil engines have been delivered at the mill of the Deadwood mines and the milling plant will probably be started soon after January 1, 1911. The batteries and tanks are in place and the pipe-line is being laid. In the mine, cross-cutting continues on the 500-ft. level.——The Oaks Co. has opened a 5-ft. vein on the Myrtle mine. A drift is being run east at the bottom of the Abe Lincoln 100-ft. shaft on a 4-ft. vein.——The Mogollon Gold & Copper Co. expects to equip the boilers with oil burners and discontinue the use of wood as fuel.

Mogollon, November 26.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Republic Mines Corporation, operating the Lone Pine, Surprise, and other properties in Republic district, is employing a big force of men and shipping 3000 tons of ore per month to the smelters. The incline shaft, which is being sunk as rapidly as possible, is expected to reach the main orebody at a depth of 500 feet.

Republic, November 26.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The Consolidated company is making arrangements to begin shipments from the Phoenix-Amalgamated group. The ore is of low grade, but it is valuable at the Trail smelter as a flux.——The shipments of ore from the Rawhide mine were increased during the past week. A force of 180 men is now employed.——At the Athelstan mine of the New Dominion Copper Co. arrangements are being made to resume ore shipments, at least by the end of the year.——The net profits of the Hedley Gold Mining Co. for September were $27,688, making a total of $197,529 for the first nine months of the year.——The shipments of ore from the Boundary district for the week ended November 19 were: Granby mines, 18,352 tons; Jackpot, 714; Mother Lode, 9335; No. 7, 26; Rawhide, 4200; Snowshoe, 2400.

Phoenix, November 26.

(Special Correspondence.)—The usual conditions prevailed at Rossland during the past week, the Centre Star-War Eagle, Le Roi No. 2, Ltd., Le Roi, and Nickel Plate shipping, with work going on at the Mayflower, I. X. L. Cliff, and other properties.——At the Trail smelter of the Consolidated company about 1300 tons of mixed ore per day is being treated. Over 400,000 tons has been treated thus far this year, which is in excess of last year's tonnage.——The shipments of ore and concentrate from this district for the week ended November 19 were as follows: Centre Star-War Eagle, 4118 tons; Le Roi No. 2, Ltd. (part concentrated), 596; Le Roi mine, 339; Nickel Plate lease, 30 tons.

Rossland, November 25.

MEXICO

DURANGO

Assurances are given in Mexico City that the Mexico International next year will extend its railroad from Tepehuanes to Guanacevi, the latter being an important mining and milling centre some 60 miles from the former.——La Union mine at Indé is sending 25 to 30 tons of sulphide ore to the La Roca smelter.

HIDALGO

The Real del Monte of Pachuca has awarded to the Pachuca Foundry Co. the contract for erecting an aerial tramway from the Barron mine to the former's Loreto mill in the upper part of the town. This mine is in the eastern part of the Pachuca district, being one of the Real del Monte's several properties. The tramway to be built will be between three and four miles long, and will have steel towers; its capacity will be 40 tons per hour.

GUERRERO

The Guerrero M. & M. Co., controlled by Colin Timmons, has developed two shoots of ore in Las Varones mine, an antigua that was operated 100 years ago. One shoot is reported to be 490 ft. long and 11 ft. wide; the other 360 ft. long and 4 ft. wide. The ore contains silver and gold and is said to exceed $30 per ton. Mr. Timmons has purchased and shipped to the property a Lane slow speed mill and other equipment. The mine is out some distance from Taxco.

CENTRAL AMERICA

COSTA RICA

(Special Correspondence.)—The Montezuma Mines of Costa Rica, for the month of October, continued mining and development on the Montezuma, San Rafael, and San Juan veins. The ore trammed from the mine to the mill-bins for this month amounted to 1326 tons, of which 1215 tons was treated, the mill feed sampling $8.76 per ton. The tailing averaged $0.84, the apparent extraction was $7.92, the gross production being $9642.80. It is stated that the November tonnage will be much larger than that of the previous month. The cyanide consumption for October was 4¼ lb., but this high figure is said to be due to the higher percentage of cyanide in solution at the end of the month. Sodium cyanide is being used this year. On October 20 the zinc boxes were cleaned up, and the 696 lb. of precipitate, averaging 0.55 oz. gold and 1.2 oz. silver per pound, was shipped to New York. The mining cost was $3.50; milling, $2.92; total, $6.42 per ton.

Montezuma, November 1.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

MARK R. LAMB is at Callao, Peru.

SCOTT TURNER is at Lansing, Michigan.

S. H. BALL is in London, having returned from Siberia.

J. P. HUTCHINS has returned to New York from London.

FRANK A. KEITH has returned to Los Angeles from Mexico.

H. KILBURN SCOTT has left for Brazil on professional business.

S. E. BRETHERTON has returned to San Francisco from Sonora, Mexico.

O. H. PACKER is examining the Alpha mine at Sutter Creek, California.

BULKLEY WELLS, of Denver, was at the St. Francis in San Francisco last week.

N. TRELOAR, superintendent for Calaveras Copper Co., Copperopolis, is in San Francisco at the St. Francis.

L. L. HUTCHINSON has resigned from the Oklahoma Geological Survey to engage in private professional work.

G. F. ROWE is to examine the Mason Valley mines at Yerington, Nevada, and the Inspiration at Globe, Arizona.

R. H. CHAPMAN has completed his season's work in British Columbia for the Canadian Geological Survey and gone to Ottawa.

S. B. CHRISTY has been confined to his home at Berkeley, California, by sickness thought to be due to ptomaine poisoning.

BRAYTON P. CAMPBELL was in San Francisco this week on his way to National, Nevada, where he will have charge of the National mill.

C. H. C. MULLER and GILMORE GOODLAND, of London, are in New York on the way to Mexico to examine the properties of the Batopilas Mining Company.

C. A. WECK, superintendent for the Bluestone Mining & Smelting Co., at Yerington, Nevada, has returned from a visit to the Globe and Miami districts, Arizona.

F. OSKAR MARTIN, mineral inspector for the General Land Office, has returned to San Francisco from an examination of quicksilver deposits in Lake and Sonoma counties.

FITZ JAMES MCCARTHY, widely known in mining circles of the West as 'Fitz Mac,' died at Phoenix, Arizona, November 13. As a newspaper writer on mining topics he had done much to advertise the West.

OBITUARY

ALMON D. HODGES, who was born at Providence, Rhode Island, in 1843 and died at Roxbury, Massachusetts, November 7, was especially well known to the mining engineers of the Pacific Coast. After graduating at Harvard, serving in the Civil War, and studying at Freiberg, he came to San Francisco in 1869. For three years he was connected with the *Mining and Scientific Press*, first as associate editor and later as editor. Although he was then but a beginner his work was characterized by accuracy in technical matters and style which made his writings a delight to readers. In our anniversary number of May 21, 1910, Mr. Hodges gave some account of San Francisco as he knew it at that time and penned a charming and graphic picture. In 1871 he left the *Mining and Scientific Press* to take up engineering work, beginning, as he has related, as a workman in one of the Comstock mills in order to remove the taint of schooling and obtain recognition as a 'practical man.' This came quickly, and his practice in subsequent years extended over the whole West as well as abroad. Some years ago he retired from general work, although he retained some consulting practice to the end. He lived in Boston, but was a frequent visitor in San Francisco, where he had many friends and club associates.

TABLE OF CONTENTS

EDITORIAL

MINNEAPOLIS is to entertain, December 27 to 31, the American Association for the Advancement of Science, that wonderfully complex organization which meets annually to prove that vice-presidents are not negligible.

PORCUPINE is to have a railway at once, as Ontario authorities have passed an order in council authorizing construction of a line from Kelso and appropriating $450,000 for that purpose. In the meantime, the wagon-road is reported to be in good condition and the eight-mile tramp through the mud will soon be a thing of the past.

LOST HILLS is attracting much attention and an important addition to California oilfields is widely expected. Numerous strings of tools are working and the area will be thoroughly prospected. So far there is one producing well. It yields an excellent oil that finds ready local sale for fuel on other locations. This well is shallow, approximately 500 feet in depth, and it is suspected that the oil is from a minor body of sand in the shale, the true oil sand lying deeper.

RAILWAY managers smiled broadly when Mr. Louis D. Brandies maintained that better methods of operation would lead to such saving as to make higher rates unnecessary. They challenged him to make good his statement and he has accepted the challenge by offering to serve without pay while pointing out the economies needed. Any attentive reader of *The Engineering Magazine* in particular will need no great argument to convince him that Mr. Brandies has much with which to back his statement. What the Santa Fé officers have done in shop economy should surely be possible elsewhere, and why should it cost one railway four times as much to repair its locomotives as it does another? The railways are large institutions and however earnestly a manager may be working, he is a bold man who says another can not show him a better way.

COST DATA of considerable interest are contained in the annual report of the Nevada Consolidated Copper Company. The cost of direct mining, mostly by steam-shovels, was 15.4 cents per ton of ore, but to this must be added 15 cents for stripping redemption. Not only has it been necessary to strip the overburden from the ore, but a large amount of waste has had to be removed from around the rim of several of the great pits to safeguard the workmen at the bottom, which could not be done without giving the walls of the pits the

proper slope angle. Stripping has cost 47.6 cents per cubic yard, equivalent to 20.3 cents per ton. It is expected this will be reduced. The cost of concentration was about 61.7 cents and of smelting 59.3 cents per ton of ore. It is interesting to note that the smelting was all done in matting reverberatories. The blast-furnace was completed during the year but was not blown in.

ELSEWHERE in this issue will be found a translation, by Mr. W. H. Shockley, of an article which recently appeared in *Zoloto i Platina*, the quasi-official publication of the Russian gold and platinum producers. The subject of the translation is the 'Production of Ural and Siberian Dredges for 1909.' In the original publication the article was followed by a translation into Russian of an article by Mr. W. M. Knox on 'Less Known Dredges in California,' which appeared in the *Mining and Scientific Press* of July 2, 1910. It is gratifying to know that many of the technical articles published in the *Mining and Scientific Press* are translated and re-printed in *Zoloto i Platina*. In turn, the translation into English of an article from the Russian publication will undoubtedly be of interest and value to the many American and other English-speaking engineers now in Siberia and Russia.

IRON ORE receipts at lower Lake ports in 1910, to the end of October, amounted to 38,388,162 long tons, compared with 34,569,354 for the corresponding months in 1909. Of the total amount 82 per cent was unloaded at Lake Erie ports. The receipts at Gary, Indiana, show a curious decrease, and indicate that the new plant is slow in getting up speed. On another page we present a general review of the great Minnesota ranges that are now dominant as iron-ore producers. It is peculiarly appropriate that it should be written by a member of the faculty of the University of Minnesota, since that institution is owner of large areas of iron-ore land. It has in prospect from royalties so many millions as to cause officials of other Universities spasms of envy. With the money comes responsibility, and the University will not deserve its good fortune unless it use every effort to build up its mining school and in other ways give aid to the industry furnishing the funds. We are glad to know that a reorganization and enlargement of the geological department is now under way, and we hope the whole school of mines may be touched up. Minnesota deserves, and has the money to command, the services of the best men in the profession. A unique opportunity will be sacrificed if they be not secured.

DRILLING oil wells is a business concerning which technical literature has had little to say. In general, the work has been in charge of mechanics rather than engineers, and there are so many ways in which a driller can either help or hinder the work that the men have generally been given a free hand. Usually, too, when a field is under development speed is all-important. Competent drill-men have had neither time nor inclination to write of their work. In this issue Mr. W. R. Jewell tells something of the methods adopted in California and quotes representative costs. Detailed figures necessarily vary from point to point, and there are so many contingencies that accurate estimates can not always be made. It should be remembered that the drill crew works in the dark. It is impossible either to see the bit at work or to examine the hole when completed and determine just what was the difficulty. Among other notable things accomplished under these conditions, are the handling of a free-swinging column of eight-inch pipe half to three-quarters of a mile long; passing such a pipe to one side and around broken casing or tools in the bottom and continuing the hole; cementing off heavy flows of water nearly a mile below the surface; picking up from the bottom broken tools; underreaming so as to advance casing, and many other equally striking things. In California, wells have been completed where the pipe was broken and passed seven times, and yet a casing was landed successfully at the bottom. The technical achievements of the oil-men deserve more notice than they have received.

Conflicting Estimates of Ore Reserves

The Utah Consolidated Mining Company is the last big mine to get into trouble over ore reserves. The price of shares has dropped from $79, the high mark of January 1907, to $15, and profits per share from $9.45 in 1906 to $0.51 in 1909. Some of this decrease is properly chargeable to the lower prevailing price of metal, some to the necessity for dismantling the company's smelter, and some to the decrease in the metal content of the ore. The 296,989 tons mined in 1906, yielded at the rate of 62.4 pounds of copper per ton, with 1.6 ounces of silver and $2.87 of gold. In 1909 the corresponding figures were 35.8 copper, 1.07 silver, and $1.54 gold. These facts alone would be sufficient to depress the value of the shares. There is, however, the further matter of revising estimates of ore reserves. According to a statement issued by Mr. U. H. Broughton, president of the company, Mr. J. B. Risque, till recently the manager, estimated the reserve at 1,237,470 tons, early this year. This estimate was checked in February by Mr. J. W. Finch, who placed the amount at 1,121,360 tons. Since that date 130,000 tons has been mined. Mr. R. H. Channing, on his recent return to the property after an absence of a few years, questioned these figures, and Mr. C. C. Burger was employed to make a new examination. On the basis of reports by Mr. Channing and Mr. Burger the reserves are now placed at 300,000 tons averaging 2.32 per cent copper, $0.50 gold, and 0.85 ounce silver. From the large tonnage shown by mine maps and records to exist, but now inaccessible for inspection, it is estimated that 100,000 to 250,000 additional tons will be recovered. It is difficult to reconcile these conflicting estimates despite the high standing of the various engineers concerned. Evidently the principal difference is in opinion as to the amount that may be recovered from the workings not now accessible. The only evidence upon

which Mr. Risque, Mr. Finch, and the others could base an opinion consisted necessarily of old maps and records, some of which antedated Mr. Risque's administration. If they were inaccurate and untrustworthy, former managers of the property are the ones at fault. If the data were accurate but were wrongly used, one or the other of the sets of examining engineers has made a serious mistake. Pending explanation by the men concerned it is well to suspend judgment, though the incident emphasizes anew the extreme danger of any engineer basing estimates upon figures furnished him by another.

Report of the Secretary of the Interior

Recommendations made by the Secretary of the Interior regarding proposed changes in laws relating to mineral lands, are summarized on another page. It will be noted that the Secretary neither favors nor anticipates extensive changes in the laws relating to lode and placer locations, except that he suggests that forty acres be made the maximum which may be acquired by any individual or association under the placer-land laws. This recommendation will meet with opposition. Under the modern scale of development more, rather than less, land is needed for each industrial unit. Forty acres would be too small an area to warrant building a modern dredge or driving one of the long cross-cuts necessary in drift mining. It would be better to change the terms under which land is given, if any change be desired, rather than so to disregard the practical conditions that must be met in conducting a modern industry. There may be a question why the Government should give land to anyone; but to apportion it in lots too small to be economically utilized, merely burdens the industry with expenses incident to consolidation of small holdings. Under existing conditions it means that the Government provides locators with the means of practically blackmailing those who would develop a large industry. Would it not be more businesslike to bargain directly with the men who are to conduct the enterprise and apply the profits to reduction of taxes paid by the 'poor prospector'? If it be felt that this does not sufficiently reward him, an old-age pension or a monthly stipend would probably answer, and the plan would have the advantage of letting each one know exactly what the true cost is. As it is, the 'poor prospector' is too often but the stalking-horse of those who would get something for nothing.

Other recommendations of the Secretary will meet with more general approval. His suggestion that more be appropriated for the National Parks in an effort to keep at home some of the money spent on foreign travel, his proposal that the smaller parks be given to the States, his recommendation that mineral location notices be filed in the nearest land office and a limit be set to the time that land may be held by assessment work, are all sound and should be adopted. The proposal to allow land cases to be taken to the Court of Appeals of the District of Columbia should be promptly enacted into law. Opposition among Western members of Congress who wish instead to allow appeal to Western courts, is likely only to prevent any provision for court review. The District court may well come in time to be especially competent to handle such matters and there will be advantage in having cases tried at the capital where complete records are available. To insist on general review by Western courts indicates some fear as to the soundness of the cases to be tried. The reason for taking such matters into court is to secure judgment by men expert in the law and wholly disinterested. If it be wrong that the Department of the Interior should be judge, jury, and prosecutor, and we believe it is, what can be said for insistence that cases shall be appealed only to courts most likely to be influenced by local public opinion and custom?

The Secretary does not favor the leasing of public coal lands, except possibly in Alaska. He does, however, believe in leasing the remaining oil-bearing lands, and points to the success of the system in Oklahoma. He believes that the States should assume a large burden in connection with conservation measures and suggests that California make consumption of oil a public use and undertake the regulation of prices. This impresses us as a large order for California, and while we believe that the police power of the State must be used to curb monopoly, the law of supply and demand will always be potent. The United States as a large owner of oil and coal land has the power by stimulating or retarding development to directly influence supply, and so, price. If it be conceded that it is desirable to undertake regulation of price, why abandon the natural means of doing so? This year the peculiar combination of law and land office decisions has forced development at many points in California oilfields at a rate not warranted by the price of crude oil. Why should the United States withdraw land, thereby shutting off additional supplies of oil, and expect the State to use its police power to prevent the price from rising? Or, to present the reverse, why should land be thrown open to unlimited development and the State be expected to secure for producers a 'fair price'? Ownership of the land is the key to the situation. What good reason may be urged for opening the door, throwing the key down the well, and then expecting the police to keep out burglars? Not that all these arguments and inquiries follow from Mr. Ballinger's recommendation. They have force rather against those who would rely exclusively on the State's police power. The time may well come when it will be wise to make each State a trustee with control of all the public land in its borders, but for the present the power of the United States and of the States severally, is needed to control the situation. Unpopular as the proposal undoubtedly is in California, we believe that the plan for the Government itself to lease the oil land is sound, and as a present means of meeting the situation, should be adopted. We are glad to be in accord with the Secretary in this, though we would again suggest that the matter is one that may well be deferred until the present difficulties of the oil men have been met.

Production of Ural and Siberian Dredges for 1909

Production of Ural and Siberian Dredges for 1909

Translated by W. H. Shockley

*Following the example of last year, the Permanent Consulting Board of Gold and Platinum Producers has prepared statistics of the production of dredges in 1909. As dredging has been carried on in Russia for some ten years the present is a fitting time to sum up and explain the statistics, and to show the importance of dredging for gold and platinum mining in general, and to give some account of special districts. The editors hope in the near future to publish an article in which the above questions will be fully considered, and special attention will be given to important data, which have been collected by the Consulting Bureau with regard to the production of dredges during the last four years. The following short remarks give some explanation of the table, on pages 764-765, of production of the Ural and Siberian dredges for 1909. The questions sent out by the Consulting Bureau were answered by 23 operators, controlling 48 dredges. The following operators did not send returns:

1. The Platinum Company; no reason given.

2. Verkotursk company; because of liquidation (the dredge has been transferred to the Neviansk Works).

3. Teptiarsk Gold Mining Co.; on account of the stopping of dredging.

4. Putiloff Works; gave the same reason as the last.

5. Yenesei Gold Mining Co.; no explanation given.

The above owners control altogether seven dredges. In all there are registered 55 dredges. This is rather less than the number registered last year. This shortage of dredges is accounted for by the less number of dredges worked by the three large companies, namely, Draga; Fedorovsk; and the Neviansk Works. Comparison of the results of working during the last four years yields the following table:

	1906.	1907.	1908.	1909.
Average number of hours worked by one dredge	2,837,16	2,259.23	2,502.24	2,771.7
Average number of cubic yards of sand washed by one dredge 159,588		139,274	166,410	186,939
Average production of metal by one dredge, oz.	1,346	1,141	1,434	1,811

From the above table it follows that while the average excavation, for 1909 as compared with 1908, has increased 20,529 cu. yd., or 12.4%, the average production has increased 377 oz., or 26.2%. These figures show that the output of gold has increased twice as much as the increase in the amount of material treated. From this it may be concluded that the gold-dredging operators, taught by bitter experience, have worked richer ground. Actually the average content of gold for a cubic yard has increased to 17.8c. in 1909 as compared with 15.9c. in 1908. An output of 1810 oz. by one dredge should be enough to cover working expenses and amortization, and to allow some profit. The figures given above for the production of dredges for 1909 show that the dredging industry was unquestionably successful, both technically and economically. Following is a classification of the dredges according to the amount of gold produced:

Output.	Dredges.
Less than 527 oz.....	6
From 527 to 790 oz.....	2
" 790 " 1053 "	5
" 1053 " 1317 "	8
" 1317 " 1580 "	4
" 1580 " 1843 "	4
" 1843 " 2107 "	6
" 2107 " 2370 "	5
" 2370 " 2633 "	2
" 2633 " 2897 "	2
" 2897 " 3160 "	1
" 3160 " 3423 "	1
1 dredge gave gold and platinum 6180 oz.....	1
1 dredge gave gold and platinum 7321 oz.....	1
Total	48

*From 'Gold and Platinum (Zoloto i Platina)', No. 17, September 1910.

STANDARD OIL

The dividend of $10 per share for the last quarter of this year to be paid by Standard Oil Co. on December 15 will make total disbursements to shareholders from 1902 to 1910, inclusive, of $357,929,620. Standard Oil Co. within that period has paid more to shareholders than any other corporation in existence, although the U. S. Steel Corporation is paying more per year in dividends at present. The preferred and common dividends of the U. S. Steel Corporation amount to close to $51,000,000 per year, while Standard Oil Co. pays a trifle less than $40,000,000 per year. From 1881 to 1910, inclusive, Standard Oil Co. has paid out $710,000,000 in dividends and its total net profits during that period, with 1907, 1908, 1909, 1910 estimated, aggregated a total of $1,100,000,000, which, after payment of dividends, leaves a surplus of $420,000,000. Of this surplus more than $315,000,000 has been accumulated over the last nine years. This shows the great increased earning power of the Standard Oil during late years. The following shows net profits, dividends paid, and surplus after dividends of Standard Oil Co. from 1882 to 1910, inclusive, as compiled by the *Boston News Bureau*, earnings for 1907, 1908, 1909, and 1910 being estimated:

Year.	Profits.	Dividends.	After div. surplus.
*1910	$80,000,000	$39,335,320	$40,664,680
*1909	80,000,000	39,335,320	40,664,680
*1908	80,000,000	39,335,320	40,664,680
*1907	85,000,000	39,335,320	45,664,680
1906	83,122,251	39,335,320	43,786,931
1905	57,459,340	39,335,320	18,481,026
1904	61,670,110	35,188,266	26,481,844
1903	81,336,994	42,877,478	38,549,516
1902	64,608,363	43,851,976	20,761,407
Total	$273,302,064	$357,929,620	$315,272,444
1882-1901, inc.	456,240,000	351,883,000	104,407,000
Total $1,129,442,000		$709,812,620	$119,679,441

*Estimated.

Iron Mining in Minnesota

By E. K. Soper

Modern science, coupled with skilled engineering practice, is constantly devising new methods and new machinery for harnessing the forces of nature and converting her resources into products useful to man. In this never ceasing advance, mining has more than kept the pace, and many deposits of the useful metals which ten or fifteen years ago were considered too low grade or refractory to be worked, are now being mined at a handsome profit, while the price of other metals has been reduced owing to the application of cheaper and better methods of mining and reduction of the ore. While the great majority of ores will always have to be mined by underground methods, it has been possible in the case of certain deposits, to apply a cheaper and quicker method of extraction, excavating in open pits with steam-shovels. This method is being used in mining certain iron and copper deposits, principally the former, where the ore lies at or near the surface and is easily broken.

The United States produces nearly twice as much iron ore as any other country in the world, and most of this comes from the Lake Superior region in Minnesota, Michigan, and Wisconsin. Minnesota is by far the most important producer of iron in the Union. St. Louis county alone produces three-fifths of the Minnesota ore, the shipments during 1909 amounting to 29,282,526 tons. There are two distinct producing districts or 'ranges' in northern Minnesota known as the Mesabi and Vermilion. From another, the Cuyuna, in Crow Wing county, about 100 miles west of Duluth, shipments have recently begun.

Mining on the Vermilion range, which marked the first iron mining in Minnesota, began in 1884 when the Soudan mine was opened near the town of Tower.

Mahoning Mine, Hibbing, Minnesota. Showing Spiral Arrangement of Tracks.

Stripping at the Shenango Mine, Chisholm, Minnesota.

Stripping and Mining at the Same Time. Shenango Mine.

Later the Ely district was opened. The region was reached by the Duluth & Iron Range railroad, which at first was built only as far as Tower, but was later extended a few miles beyond Ely. There are now six producing mines on the Vermilion range all controlled by the United States Steel Corporation and operating under the name of the Oliver Iron Mining Co. Up to the first of January 1910 these mines produced a total of 29,125,000 tons of iron ore. By far the most important of the Minnesota ranges is the Mesabi. The first ore from here was shipped from the Mountain Iron mine over the Duluth, Missabe & Northern railroad in 1892. That year the total shipments were 4248 tons. At present there are 92 producing properties on the Mesabi range from which during 1909 were extracted 28,174,000 tons. Since

1892 the shipments from the Mesabi have amounted to the stupendous total of 195,700,000 tons of iron ore. Add to this the production of the Vermilion and there is a grand total of 224,825,000 tons sent to the smelters from Minnesota since the beginning of operations. Stated merely as a matter of figures, it is almost impossible to conceive what this means, but if all this ore were loaded and put into one train made up of cars of ordinary size holding 50 tons each, it would extend for 19,360 miles. If this train were arranged on the latitude line of St. Paul it would reach around the earth and have nearly 1700 miles to spare.

The Minnesota ores consist chiefly of the mineral hematite (Fe_2O_3), which contains theoretically, when pure, 70% iron and 30% oxygen. The orebodies of the two ranges are very dissimilar. In the Vermilion district they are quite narrow as a rule, and extend to considerable depths, usually standing at a high angle to the horizontal, while the ore is hard. This fact has necessitated the adoption of underground methods of mining. On the other hand, in the Mesabi district, the orebodies are beds from a few inches to 300 ft. thick, occupying broad, shallow troughs between quartzite and slate. The underlying rock is usually a hard iron-bearing chert called taconite, while the deposits are everywhere overlain by a thick mantle of glacial drift composed of material varying in size from fine sand to boulders weighing several tons. The ore is usually soft. Many theories have been advanced to explain the origin of the Mesabi deposits, but the one generally accepted by geologists is that the ores are due to the alteration of a rock composed of granules of green hydrated ferrous silicate called greenalite, which was originally laid down in a shallow sea as a sedimentary deposit. The alteration of this rock by percolating underground waters, caused a concentration of the iron and a removal of the silica from the original greenalite, and thus gradually, through geologic ages, the immensely rich deposits of iron ore were formed. The deposits have a lateral extent considerably greater than the vertical, and this fact makes possible in many cases the use of open-pit methods of mining. The thickness of the overlying glacial drift or 'surface,' as it is called, varies from 10 to 200 ft., with an average of about 100. This drift must all be removed and the surface of the clean ore exposed before actual mining may begin if steam-shovel work is to be adopted. Since the average property contains 40 acres, and many contain two or three 'forties,' it will be readily seen that the stripping from such an area of a thickness of 100 ft. of drift is a stupendous task. This is the chief disadvantage of the open-pit method of mining, for the interest on capital invested in preliminary plant and operations before a single ton of ore can be mined is sometimes prohibitive. Again, if there are ledges or horses of barren rock projecting into the ore, or if there are long narrow lenses and tongues of ore extending into the rock, open-pit mining is impracticable. Hence, many large mines throughout the entire district are being operated by underground methods, while some combine with the underground method, open-pit and milling systems. The nature of the deposit is determined beforehand by drilling holes through the ore at regular intervals over the area and from the results of this drilling, the size and shape of the deposit is estimated and the best and cheapest method of mining determined.

In stripping, it has been proved that it will pay to remove about two feet of overburden for every foot of ore. In other words, given a deposit of average grade, size, and shape, it will pay to strip off 100 ft. of glacial drift if ore 50 ft. thick can be thus obtained. Much of the stripping is done by contract at prices varying from 25 to 35c. per cubic yard. The stripping is loaded into dump cars holding about 7 cu. yd. and hauled to the dump, which must be situated on ground that is not underlain by ore. Also the dump must not be too far distant from the pit or the cost of hauling will be too great. The drift is hauled out of the pit in trains of from 6 to 12 cars, by 'dinkey' locomotives weighing from 12 to 25 tons. Lately, the stripping contractors have been using Baldwin or American locomotives weighing 50 tons, and no doubt the dinkeys will soon be entirely superseded by the larger locomotives. Sixty to eighty-pound steel rails, standard gauge, are used in all the pit work except where contract work on stripping is being done with dinkey locomotives, when 40 to 60-lb. rails on a 36-in. gauge are sometimes used. The steam-shovels in use are either of Bucyrus or Marion type. The one most in use is a 90-ton shovel with a 2½-cu. yd. dipper. These will average 35,000 cu. yd. of drift, or 50,000 tons of ore per month. In figuring the weight of ore and sand, it is estimated that 13 cu. ft. of ore of average grade will equal one ton, while 1 cu. yd. of sand is required to give the same weight. The ore is loaded directly into steel railroad cars of 50 tons capacity, which are brought into the pits by a system of switchbacks. The grades for the track vary as widely as do the shapes of the pits, but the minimum grade possible is always used. A ½ to 2% grade (average 1½%) is in use at the Hull-Rust mine at Hibbing, which is the largest iron mine in the world. This grade is perhaps a little below the average for the district and permits of hauling from the pit 10 to 12 cars of 50 tons capacity each, by one 90-ton locomotive, with the occasional use of a helper. In most of the mines, the usual number of cars hauled from the pits by one locomotive is six.

In classifying the ore for shipment, all ore above 49% iron by weight is considered of commercial grade. The arbitrary limits given below for separation of the ore into bessemer and non-bessemer grades are those used by the Oliver Iron Mining Co. during the summer of 1908 in making ore reserve estimates for the ensuing five years.

	Iron, per cent.	Phosphorus, per cent.	Silica, per cent.	Manganese, per cent.
Bessemer	61.55	0.052	4.65	1.59
Non-bessemer ...	57.20	0.099	7.15	1.04

The ore in front of the shovels is sampled frequently and thus classified and loaded into cars, according to the grade. The phosphorus and silica are as important in the classification as the iron content,

and ore that is high enough in iron to be graded as first class may be rendered second class on account of an excess of these elements.

Since the Mesabi range was opened, there has been removed 118,500,000 cu. yd. of stripping. In 1909 the U. S. Steel Corporation handled 22,000,000 cu. yd. From the following figures it may be readily seen that the operations on the Mesabi, taking into account the removal of ore, are far more extensive than the work conducted at the Panama Canal.

MESABI RANGE

	Cubic yards.
Stripping by all concerns (1909)	30,000,000
Equivalent 28,174,000 tons ore	19,750,000
Total material removed (1909)	49,750,000

PANAMA CANAL

Total material removed during 1909	35,100,000

The above figures do not tell the whole story. In addition to all this work, it must be remembered that previous to mining, the land has to be thoroughly explored before any operations can be conducted. Drill-holes by the score have to be put down on each individual property of any size, and a large proportion never shows anything of value. The U. S. Steel Corporation spends yearly in Minnesota alone nearly $1,000,000 in exploration, most of which goes for drilling. In the period from 1910 to 1909 inclusive, this concern has put down drill-holes which have an aggregate length of 229 miles. Some of this work was done on the new Cuyuna range. There are few surface indications to guide the prospector. The covering of gravel has completely obliterated the outcrops of the iron-bearing formation. Scattered through this drift are pebbles of the iron formation, and these may serve as a rough guide at least in tracing the north boundary of the formation. Again, there seems to be a tendency for the larger orebodies to underlie surface depressions rather than elevations, but there are notable exceptions to this rule. For drilling, the property is usually surveyed into 100-ft. squares and a drill-hole put down on the corner of each square. The first holes are put down on adjacent corners, and unless ore is found, all of the corners are not drilled. Churn-drills are used in sinking through the drift and ore, while diamond-drills are used on hard rock or boulders. The drilling is usually done by contract, and there are several large exploration companies in the field ready to do this work. The contract price for drilling varies from $3 per foot in drift and ore to $6 per foot in rock.

Many of the mines are owned in fee by the State and many more by individuals or corporations, notable among the latter being the Great Northern railroad. The property is leased to the operators on the basis of a royalty of from 25c. to $1 per ton of ore mined, the higher figure representing some of the more recent leases. The aggregate tonnage of merchantable ore proved by exploration on the State properties alone is, according to the Tax Commission compilation, 137,495,000 tons. This will in time be the means of a large revenue for the State.

Three railroads tap the iron ranges of Minnesota. (1) Duluth & Iron Range; (2) Duluth, Missabe & Northern; (3) Great Northern (Mesabi division). The ore is transported to the docks on Lake Superior, where it is carried by boats to Lake Erie points and South Chicago. The Duluth & Iron Range docks are situated at Two Harbors, Minnesota, and have a total storage capacity of 231,656 tons. The ore docks of the Duluth, Missabe & Northern are at Duluth, with a capacity of 269,034 tons. The Great Northern docks are at Superior, Wisconsin, and the total capacity is 283,500 tons. Some of these docks represent a cost of about $1,000,000. There is a fleet of 550 boats on the Great Lakes which transports the ore to the Erie ports, where it is re-loaded into cars and shipped by rail to the furnaces to be converted into pig iron and later to finished iron and steel. The average ore-boat holds about 8300 tons and is loaded in six hours. The newer boats which are being added to the fleet have a much greater capacity. The cost of these steamers varies from $200,000 to $500,000.

The importance of Minnesota as a producer of iron ore is fixed for many years. If the new Cuyuna range proves to be as rich in iron as is predicted for it, Minnesota will be in the enviable position of furnishing more iron than any entire nation in the world, except, of course, the United States. Recently work has been started on a $10,000,000 steel plant to be erected at West Duluth by the U. S. Steel Corporation, and in a few years Minnesota will be manufacturing steel out of the ore from its own mines.

UTAH COPPER CO.

The October production of the Utah Copper Co. was 7,582,219 lb., compared with 7,077,035 in September. The output last month represents an increase of 505,184 lb., or 7.1% over September, but a reduction of 14.5%, compared with the record output of 8,862,900 lb. last May.

The production by months in 1909 and 1910 was as follows:

	1910.	1909.
January	4,745,066	3,963,673
February	5,913,465	3,143,127
March	7,853,288	5,000,749
April	7,902,643	4,185,895
May	8,862,900	4,355,507
June	8,460,879	5,233,010
July	8,677,851	4,354,163
August	7,440,035	5,162,598
September	7,077,035	5,282,913
October	7,582,219	5,252,755
Total	74,515,381	46,434,380

Superficial alteration of gold deposits and the migration of gold, take place at low temperatures, according to W. H. Emmons, who has recently studied the subject. At the very surface the temperatures range from 0 to 50° C., and pressures do not exceed one atmosphere. At the normal gradient of increase, the temperatures, even several thousand feet below water-level, would not exceed 100° C., and in the main are considerably lower. The general character and, approximately, the concentration of the solution are known from analyses of mine-waters.

The Clifton-Morenci District of Arizona—I

By William L. Tovote

Since the publication of the classic report on the copper deposits of the Clifton-Morenci district by Waldemar Lindgren, in 1905, the camp has developed in a quiet but steady way. It is to be regretted that it lies so far off the main traveled routes, for on account of its rather quiet progress it does not hold the professional eye like some other camps of no greater size or economic importance. This is the more unfortunate because the district affords interesting geological problems and here, too, are to be found, in places, new and up-to-date mining methods.

I. Geology.—Geologically Morenci presents much the same series of rocks that is found all over the Southwest. Of the pre-Cambrian crystalline schists but small remnants are found and these out-

The Morenci District.

side of the mining area proper. The sedimentary series is represented by the basal Cambrian conglomerate, followed by Cambrian quartzite, the Paleozoic limestones and shales, the sediments culminating in the Upper Carboniferous limestone. During a long continental period, from Carboniferous to Cretaceous, there is no positive proof of sedimentation. There was a period of uplift, however, for the Cretaceous series rests unconformably upon the Lower Carboniferous at Morenci, where the Upper Carboniferous is absent. However, the Cretaceous and the following Tertiary conglomerate, introducing the present continental period, have only a negative interest for the mining man, as the copper-bearing solutions did not penetrate into these rocks, and they only obscure the extension of the older sediments. Into this sedimentary series was intruded eruptive rocks, that may be divided roughly into three groups: first, the granite, of Cambrian or pre-Cambrian age; next, the porphyries and diabases, intruded in late Cretaceous or early Tertiary, initiating the ore deposition, and last—of no economic interest—intrusions and flows of rhyolites, andesites, and basalts, covering large areas and forming, with the Gila conglomerate, a wide circle, out of which rise the older formations, in which the mining is now carried on.

The productive area is not large. Allowing for some undeveloped prospects, the mineralized belt extends, perhaps, five miles in a southwesterly direction, with an average width of about two, but only a few hundred acres out of this large area form the source of the present copper output, which is from three main groups. The first is the central porphyry belt with its adjoining sedimentary blocks, where are situated Morenci, Metcalf, and Shannon, and farther north the Mammoth group. This is flanked on both sides by granite belts. That on the eastern side includes the second district in which are the Copper King, the Lezinsky group, Antietam, and Boulder mines, none of which is producing largely up to now. In the western granite belt occurs the Coronado mines, the Pyramid, Santa Rosa, and Cuprito groups, constituting the third great district. The whole area is cut by a complicated system of faulting, that breaks the Paleozoic sediments into blocks, which have been isolated by the settling of the surrounding country between and around the two upholding buttresses of massive granite which form the Coronado and Copper King mountains—two imposing peaks, that dominate the landscape, rising to 7500 ft. above the sea. The faults have been described in Mr. Lindgren's report, and hardly any new features have been developed since by the more extended mining operations. These faults, and the character of some of the rocks, that lend themselves easily to erosion, give the landscape its wild and rugged appearance. There is little doubt that the important metal of the camp, copper, is intimately connected with the occurrence of the porphyry injection, beginning with its intrusion and continuing for a long time, through the medium of ascending solutions, along cracks and fissures in the cooling magma and in the disturbed surrounding rocks. While the source of all the copper deposits is undoubtedly the same and the eruptions were essentially contemporaneous, even though covering a long time, the varied character of the rocks in which deposition took place, and other local conditions resulted in differences, so that there can be discerned four main groups of deposits, as follows, ranging them according to the sequence of their development to economic importance: 1. Metasomatic orebodies in the sedimentary series. 2. Porphyritic copper deposits. 3. Deposits along fault-planes accompanied by diabase intrusions. 4. Fissure veins in granite.

1. The metasomatic copper deposits in the sedimentary series gave life to the camp in the early days, when only the richest ore could be mined on account of the lack of cheap transportation. In

occurrence these deposits resemble the Bisbee type, only that they are, perhaps, more strictly limited to the immediate vicinity of porphyry intrusions. This type of ore has been practically mined out today, only the great Longfellow cave and a few of the still accessible stopes bear witness to its former richness around Morenci. Lessees are still following the ore in a few places along old stopes and in some outside localities, but the amount mined is dwindling year by year. Company-work on these orebodies is limited to Shannon hill and the Mammoth group of the Arizona Copper Co., Ltd. The ore at the latter place is distinguished by the entire absence of copper carbonates, in place of which is found chrysocolla and copper-pitch ores. The ore mined was and is entirely oxide ore, and all the known occurrences are near the surface. The economic minerals are native copper, cuprite, carbonates, chrysocolla, and brochantite, with here and there chalcocite and a few rarer minerals, mainly mixtures and combinations of copper, zinc, and iron salts. The shape of the orebodies is typical, roughly tabular, as in other metasomatic deposits with increasing vertical axes along or near intrusive dikes and fissures.

2. The porphyritic copper deposits exceed today by far every other group in economic importance in the district. A network of small fissures, occurring as lodes, or in zones of shattering and fracturing, contains chalcocite, the only mineral of economic importance for this group in Morenci proper. In and around Metcalf is mined some oxidized porphyritic ore. Here the chrysocolla is the most important mineral, carbonates and brochantite appearing in lesser degree. These oxidized ores are treated by leaching with sulphuric acid, as they are generally too poor for direct smelting, and defy concentration. The tenor of the ore treated is kept around 4% Cu where possible. Their commercial importance at present is not great, but might increase with improved methods of extraction. The chalcocite lodes are represented by numerous veinlets and a few stronger veins of roughly parallel course. The footwall is sometimes well defined, while at the hanging wall the lode usually grades into the surrounding porphyry. The terms foot and hanging wall are not well adapted for this type of deposit. The original mineralization appears to have been silicification and pyritization. The pyrite is slightly cupriferous. The chalcocitization is the result of secondary enrichment by descending surface waters. The mineralization is not limited to fissures and veinlets but penetrates the surrounding porphyry, analogous to stockwork deposits. The chalcocite envelops and penetrates the pyrite individuals and sometimes entirely replaces them in the veins, and it also penetrates the porphyry, replacing the feldspathic minerals either directly or by means of the substituted pyrite. The porphyry itself, in the vicinity of the lodes, is thoroughly altered, usually by kaolinization and serpentinization, to a soft, clayey aggregate of compact aluminous and magnesian minerals and quartz, that only roughly preserve the original structure. The porphyries vary from diorite and diorite-quartz-porphyry to monzonite and granite-porphyry with their intermediate varieties, grading by transition one into the other, all representing apparently differing phases of the same intrusion with differing magmatic segregation, caused probably by a difference in the basal rocks through which they worked their way. The diorite-porphyry variety is not considered an ore-bearer in Morenci. While the lode type of vein is at present a dominant factor at Morenci, it is probably only of local character, limited by two converging faults, the quartzite or concentrator fault to the north, and the Copper Mountain fault to the south. The first runs nearly east-west with a turn to a more northerly direction toward its western end. The latter runs northwest. Outside of this block the lode system breaks up into a number of fairly well defined fissure-veins, so that, perhaps, an exceptional tension in this down-thrown block resulted in the breaking of the rock mass into a network of small veins, instead of a single fissure of large size. The source of the chalcocite is found in the upper part of the porphyry stock, and in the sedimentary blocks on top of it, that have since been eroded. Surface waters leached the copper from the sulphide ore, carried it in the form of sulphate, and re-deposited it farther down. This process is still going on. The upper part of the porphyry is leached out and appears at the surface as a cavernous silicious rock. The leached zone is, as a rule, about 150 ft. thick—thicker than in most other porphyritic copper camps. The underlying zone of enrichment is usually 200 to 250 ft. thick, increasing in places to about 500 ft., wherever proximity of faults or the intersection of lodes facilitated circulation and re-deposition. The width of the workable ore in the central part of Copper mountain, where the main lodes converge and intersect each other, near the Copper Mountain fault, is about 500 ft. At the lower end the chalcocite zone changes rather abruptly into cupriferous pyrite of no present economic value. The pyrite is, as a rule, more sharply confined to veinlets and sometimes is accompanied by vein quartz. The question whether the known chalcocite zone is the only workable deposit in the porphyry stock at Morenci proper, is a rather vital one, as parts of the camp have been so thoroughly prospected that the limitations of the probable ore are quite well defined. There have been, of course, recent discoveries of ore both vertically and laterally, thus extending the possibilities surprisingly, but, as a whole, the district shows its limitations. Mr. Lindgren rather discouraged the hopes of some of the local mining men as to the probability of a second workable zone below the pyrite that occurs at the lower limit of the chalcocite deposition, and the reasons for his conclusion are strong. I wish, however, to call attention to a few facts, that might, perhaps, lead to a more thorough discussion of this question by economic geologists and decide whether the still cherished belief of many a Morenci miner is hopeless. In the first place, the level of permanent groundwater has nowhere been reached in any of the workings of the district, so we here are still

in the dark as to the character of the deposits at that important level—whether they change into normal chalcopyrite, zincblende, and pyrite veins or not, and if so, whether they are of economic value. Furthermore, there is pyrite on top of the chalcocite zone as well as below it. True, the pyrite on top shows more evidence of leaching than that at the bottom, the latter appearing relatively fresh, but even this has undergone alteration, as indicated locally by nearly obliterated crystalline aggregates of a habit decidedly not pyritic. But I do not dare to pronounce them as formerly chalcopyrite, on the strength of the material itself. A last consideration, that appears to me most important, is the zinc problem. According to analyses published in Mr. Lindgren's report, the fresh porphyry contains a noticeable quantity of zinc—0.3% ZnS compared with 0.2% Cu_2S. The old workings show frequently efflorescences of goslarite (hydrous-zinc sulphate), but the bulk of the original zinc has disappeared to beyond the limits of present development, if I except an outlying prospect, the Producer group, the singular occurrence of the Joy blanket vein, in the Humboldt mine, and the Lone Star mine, where the present deepest workings disclosed a well-defined streak of sphalerite below the chalcocite zone. Is there not a possibility that the Morenci deposits may change from copper to zinc with increasing depth? And is it not possible that there may be found here an analogy to the limestone deposits of the Mississippi Valley, with their duplicated series of lead-zinc-iron? Of course, if there should be a second copper horizon below the chalcocite, I look for chalcopyrite as the copper mineral, and for veins, not for stockwerk-like impregnations.

3. Deposits along fault-planes accompanied by diabase intrusions. This group has recently come more and more into prominence. Its oldest and best known example is the great Coronado vein. It follows a fault-plane running east-west, on the south slope of Coronado mountain. The wide fault-zone is partly filled with crushed and kaolinized material mostly derived from the granite north wall, and is followed by an irregular diabase dike. This fault-vein has been worked for three miles with an average width of about 60 ft., while locally it expands to upward of 100 ft. wide. To the west it disappears under lava-flows, while to the east its extension is not yet established beyond a doubt, but it seems to cross a zone of stress, or weakness, a few hundred feet east of the Coronado main shaft and to split into several branches. One branch seems to pass down Coronado gulch and straight across into Metcalf hill, where it is, perhaps, connected with the ore deposition there. Other branches take a more northerly and northeasterly course and wind around the east slope of Coronado mountain, possibly connecting with some of the faults and veins, that are being exposed in the Santa Rosa group of the Detroit Copper Co. The Coronado vein is opened from its main shaft down to the 100-ft. adit level, a barren zone separating it from the oxidized ore. The character of the sulphide ore is the same as in the porphyritic ore, chalcocite encasing and replacing pyrite in kaolinized and serpentinized gangue material. The accompanying diabase, the intrusion of which Mr. Lindgren places slightly later than the porphyry eruption, forms an irregular dike, widening and thinning from point to point. It is generally much altered. Where found relatively fresh it appears as plagioclase and a dark-green pyroxene, perhaps diallage, with pronounced cleavage, with pyrite in grains and as a coating on fissure-planes. Mr. Lindgren did not believe that the diabase was intimately connected with the ore deposition, but the frequent recurrence of the same combination, as has been disclosed since, might perhaps change his idea. In the vicinity of the Coronado vein are several smaller diabase dikes that show encouraging superficial prospects. Diabase occurs, too, somewhere in the Santa Rosa group as indicated by float, but its connection with copper deposits has as yet not been proved there. Diabase rises along the quartzite fault in Morenci, where the Yankie lode joins and follows this fault, assuming its dip to the south, and forming the seat of operations for the Yankie and Longfellow mines. Diabase accompanies the Brunswick vein at Garfield, north of Metcalf, and appears in the Boulder mine, and the Dead Pine group, of the Arizona Copper Co., where recently a large body of high-grade sulphide ore has been developed, and also in the Antietam mine of the New England & Arizona Copper Co., which, perhaps, is an extension of the former, in the northeast end of the district. Indeed, the diabase is found in nearly all parts of the district and is of special interest, as the enriched zone has been proved in some of these mines to be of greater vertical depth than anywhere else in the district and deep mining seems to be assured here at least.

4. Fissure veins in granite. This group has not yet attained great economic importance, the properties, where this type of veins appears being still more or less in the stage of prospects. But one of them, the Pyramid mine of the Arizona Copper Co., near the foot of the Coronado incline, has had a good deal of development and is a fair example for this type. The original mineral seems to have been chalcopyrite instead of cupriferous pyrite, as it appears intimately mixed with chalcocite in the zone of enrichment. Besides this mixture is found a pure chalcocite. Local enrichment seems closely connected with cross-fissuring. Other examples of this type are some prospects of the Lezinsky group of claims on the west slope of Markeen (Copper King) mountain and those of the Cuprite Mining Co., in the north end of the district. The Santa Rosa group of the Detroit Copper Co., that bids fair to become one of the great producers of the camp, will most likely furnish other examples. As a mineralogical curiosity native copper occurs replacing the feldspar of the granite in this locality.

In concluding this geological sketch I may mention the Standard Copper Co. that works flat veins, near the contact of porphyry and granite; the Copper King mine, that went down 900 ft. on a fissure in granite, following a porphyry dike, which workings are on a highly silicious copper ore carrying

gold, and three new companies, namely, the Gold Belt, New York-Arizona, and Mesabi-Morenci Mining companies, that are developing a series of fissure-veins in the southwest end of the district, in which the economic mineral is gold. These veins probably furnished the material for the placer gold, that gave rise to a short-lived gold excitement in the early days of the camp. These are in and around Gold gulch, a tributary of Eagle creek.

DISCOVERY OF THE GOLD ROAD MINE

By J. C. Kennedy

One of the strange things connected with the mining industry is that some of the lodes which have developed into the most prominent mines have been discovered by accident, and sometimes by those who were not seeking veins. Probably a still larger number of bonanza, or dividend-paying veins have been discovered by ignorant, listless, often dissolute persons, who in a desultory way were prospecting, while hundreds of intelligent, earnest, energetic prospectors have toiled through winter's cold and summer's heat all their lives, suffering hardships and privations, and have finally 'passed over the Great Divide' without making their 'stake' on the hither side. The story of the discovery of the Gold Road mine northwest of Kingman, Arizona, which, so far as I know, has not been published, is of interest.

The Gold Road quartz lode is a remarkable one. It outcrops boldly and nearly vertically in a straight line for 3000 ft., being 18 ft. or more in width, and in places standing above the surface 75 ft. on one side and 40 ft. on the other. It is in plain view of the old overland road from Santa Fé, New Mexico, to San Bernardino, California, which was opened by Lieut. Beale as early as 1850. Hundreds of prospectors and others passed by this prominent reef in the fifty-odd years subsequent to the opening of the road, without discovering the auriferous character of the outcrop. Perhaps one reason why it did not attract the attention of prospectors was its great size and the white, unstained, onyx-like appearance of the quartz. In 1902 or thereabouts, a local character in Kingman was known as 'Mexican Joe,' whose family name is not recalled. He had previously done a little prospecting in a vagrant sort of way. When in town, so long as he could beg or borrow a peso he devoted most of his time to drink and three-card monte. When away from town he spent most of his time rolling cigarettes and hunting his burros. He had been on a spree in town ending in a fine case of delirium tremens. Henry Lovin, the sheriff of Mohave county, put him in jail ostensibly on a charge of vagrancy, but really to sober him. He was a long time sobering up, however, and during most of the time he consumed the county provisions with regularity and alarming voracity. Mexican Joe finally yearned for freedom and proposed to the sheriff that if he would furnish him with a 'grub-stake' he would leave town and find a mine for the sheriff and himself. The sheriff, mindful of the county's exchequer, or of his own future political prospects, considered it cheaper to go down in his pocket for the 'grub-stake' than to board his prisoner longer at the county jail. Joe was accordingly provided with about $10 worth of supplies, and started with his burros for Willow Spring, situated about three miles from the present Gold Road mine. Joe, however, was born tired and was still sick, or thought he was; so he did no prospecting, but stayed at the spring until his supplies were nearly exhausted, when it occurred to him that it would be wise to return to town and 'work' the sheriff for another 'grub-stake.' As usual in such cases, the burros were missing. He finally found them in a saddle-like depression on the apex of the huge quartz vein previously mentioned. Climbing up to the animals he dislodged a piece of quartz which he noticed was plentifully filled with native gold. A brief search revealed more of the same exciting material. He thereupon located three claims for himself and Lovin, two of them being named respectively the Gold Road and Billy Bryan. He then hastened to Kingman, where he quickly became the centre of interest, and an important personage. The two partners shipped $3000 worth of ore from three 10-ft. shafts on the claims, and not long afterward sold the claims to Mr. Burkhardt, of Los Angeles, California, for $50,000. The Mexican devoted his share of the sale to mescal and monte, and this ends his story. Lovin's share made the basis of his fortune.

Mr. Burkhardt sold to Baily & Posey for $100,000. Six months later Mr. Posey sold a one-third interest to Clarence McCormick for $100,000. A company was then organized and 52% of the stock was sold to a French syndicate for $500,000. Finally the mine came under the present control. It is now being worked by modern methods, and has a large medium-grade orebody from which the company expects to derive substantial dividends for many years to come.

EUROPEAN COPPER CONSUMPTION

According to James Lewis & Son of Liverpool the consumption of copper in Europe for the ten months ended October 31 (except in Germany where the figures are for nine months), amounted to 617,238,720 lb., an increase of 73,225,600, or 13%, over the corresponding period of 1909; 36,220,800, or 6%, over 1908; and 166,904,640, or 37%, over 1907. The European copper consumption for the first ten months of 1910 compares with the two previous years as follows (in pounds):

	1910.	1909.	1908.
England	168,902,720	125,865,600	149,607,360
France	113,167,040	107,392,320	118,746,880
Germany (9 months)	275,404,480	257,510,400	260,202,880
Other European countries	60,764,480	53,244,800	52,460,800
Total	617,238,720	544,013,120	581,017,920

Copper deposits are among the most widely distributed in Japan. They are well distributed over Honshu, Shikoku, and Kyushu, while in Formosa and Hokkaido a few scattered deposits also occur. The four important classes present are beds, metasomatic deposits, contact, metamorphic deposits, and veins. Copper has been mined in Japan for 1200 years. In 1908 the output amounted to 40,441 long tons, valued at $11,471,325.

NICARAGUAN MINING CONDITIONS

Changes in government in Nicaragua consequent on the success of the reeent revolution, have attracted renewed attention to the opportunities for mining in that country. There is already an established gold-mining industry and numerous properties have been examined in behalf of American in-

Indians Polling a Pitpan on the Piz-Piz River.

vestors. Something of the present difficulty of working in this country is indieated in the figure above showing the transportation of material in Indian canoes. The possibilities of economieal operation are, however, suggested by the second picture, showing the Siempre Viva falls. With a stable government and more numerous railroads the min-

Siempre Viva Falls and Power Station.

ing industry should greatly expand. It is said that the Lone Star mine was sold for $300,000, and other mines that have been under option were rejected less because of any doubt as to the value of the property than beeause of the unstable politieal eonditions at the time examination was made. The new president of the republic is known to favor the introduetion of foreign eapital and the local feeling is that a period of active exploration and development is opening.

There are numerous opportunities for investment in mining enterprises in Niearagua, and sueh investments would undoubtedly be profitable, if the difficulties of transportation were solved. The main trouble is that no one of these mining properties offers suffieient indueement to justify large expense in affording eheap transportation, sueh as the building of a railroad, but even this will, in time, no doubt, be accomplished.

STOCKWORKS

By J. H. Collins

*There are irregular masses, belts, or zones of 'country' rock that are traversed by numerous thin veins, or which have their numerous joints thinly lined, or that are sprinkled throughout with small spots of metalliferous substance, the whole mass being thus rendered of considerable value. An ore mass of this character is called by the Germans a 'stoek,' and a working upon such a mass a 'stockwerk,' or as the term has been adopted in England, a 'stoekwork.' Such open workings, whether upon true stoeks or upon the branching outerops of lodes, were in Cornwall formerly called 'coffins' or 'goffans,' while large underground exeavations of a similar charaeter are called 'gunnises' or 'gunnies.'

Sinee the individual strings of mineral are usually insignificant, it is necessary in stockwork mining to remove the whole mass of impregnated rock and to treat at any rate the greater portion in order to concentrate and separate its valuable contents. As the ores so distributed are often very small in quantity compared with the whole mass of the rock, for example with copper ores 1% or less and with tin ores 3 to 10 lb. of tin oxide per ton, a concurrence of favorable eircumstanees is necessary to enable them to be worked with profit—sueh as eheap labor; land of little agricultural value on which to deposit the refuse; a good outlet for the said refuse so as to keep the workings clear; a good supply of water for concentration purposes, and, if possible, water-power for crushing; a body of the impregnated rock so large as to permit of working on a considerable scale; a genial climate allowing work to be earried on without serious interruption, etc. Even with all these advantages many deposits are so poor that they remain unworked, and few will pay to work except as open quarries.

Stockworks in the west of England have only been worked for tin or copper. Tin stockworks have been worked in granite and several of its modifications, as greisen, schorlyte, and earclazyte, also in several kinds of feldspar-porphyry (elvan); they have also been worked in ordinary killas, and in that modification of this rock known as tourmaline schist. Copper stockworks have been worked in granite, in elvan, and in killas. Few of these stockworks are distinctly associated with ordinary lodes, and even when they are so associated there are indications pointing to a notable difference of date, the lodes being of subsequent origin to the mineralized ground. The chief individual strings are usually steeply inclined or even vertieal, and, as will be shown hereafter, these strings contain a notable proportion of the whole mineral eontent of the belt, and nearly the whole of that whieh is extracted or extractable by the simple methods in use, and which are nevertheless in most eases the only ones economically possible. The granite in which disseminated tin ore occurs is almost invariably altered into greisen, schorlyte, earclazyte, or zwitter.

*Abstract from 'Ore Deposits of West of England,' now being prepared.

Oil-Well Drilling in California

By William R. Jewell

Within the past ten years, the oil business has grown to such proportions that at the present time it constitutes one of the greatest sources of wealth in California. With its development and as a consequence thereof, have arisen many important questions and problems—financial, political, and technical. Of all the activities throughout the oilfields, well-drilling is of first importance. No matter how great may be the merit of an oil property, poor results, and probable failure, will follow if drilling is not intelligently prosecuted. Drilling for oil is a business, which when resolved into the many problems attending it, is seen to be something more than the mere drilling of a blind hole to indefinite depth into the earth. Dependent at the outset on situation, depth of formation, knowledge of the strata, position of water-sands and oil-sands, it is at best uncertain in its result. But the conditions enumerated being known, the most suitable method of drilling for the particular case may be selected, and barring more than the average run of mishaps, the cost of drilling may be approximately estimated.

Selecting the site for a well in unexplored territory is a very important matter, and in all cases the services of a competent geologist should be secured. I have seen wells drilled on the eroded crest of an anticline which got nothing, while wells drilled on the same quarter-section of land, but on the flanks of the same anticline, obtained commercial quantities of oil. This is especially true in the fields of the San Joaquin valley, where the formation is frequently and closely folded. In addition to determining the most advantageous position for a well, the geologist will be able to furnish useful data as to the depth at which the various strata will be penetrated. The selection of a point at which to drill in a proved field is comparatively simple and is largely a question of judgment after consulting the logs of neighboring wells. From comparison of these logs, the depth of certain strata in any part of the tract to be drilled, can usually be closely estimated; and the formation being known, the kind of drilling rig best adapted to meet the conditions, can be provided. For prospecting in territory expected to be less than 1000 or 1200 ft. deep, portable rigs are frequently used. These are of the Keystone and Star type. This sort of rig is inadequate for the handling of heavy casing, and is therefore impracticable for drilling to a greater depth, or where it is expected to finish a well for the pump. Rotary drilling, as the name implies, consists of advancing the hole by boring, instead of by percussion. This is effected through the agency of a two-blade, fan-shaped bit, known in the oilfields as a 'fish-tail' bit. The shank of this bit screws by means of machined threads into a 'tool-joint' which is from 18 to 24 in. long. This tool-joint in turn screws into the 4-in. or 6-in. drill-pipe which is the rotating shaft for the bit, and is from ¼ to ½ in. thick. These tool-joints are used to form the connection between the drilling-bit and the drill-pipe, and between every fourth joint of the drill-pipe, being especially designed to withstand the wear and tear of frequent jointing and unjointing which otherwise would soon strip the threads from the drill-pipe. When the well is at depth, and it becomes necessary to change the bit (which is frequently), the pipe and bit are pulled up by means of machinery into the 106-ft. derrick, and the tubing disconnected at the tool-joints. In drilling, water is continuously forced down the drill-pipe and ejected through two apertures in the drill-shank. This not only furnishes drilling water, but the erosive effect of the two jets of water from the drill-shank is considerable, and aids in cutting the hole. The water flows up and out of the well, carrying with it the drillings. The process of drilling by means of the standard or cable-rig consists of churning by means of a heavy drill suspended by rope or cable from the end of a 26-ft. walking-beam. This method of drilling possesses the disadvantage of having to pull the drill at intervals to remove the drillings.

Where the formation contains many boulders, 'shell', and other hard matter, the standard drilling rig is better suited to the work than the rotary drill. In shale, sand, and clay, where there are not many boulders, the rotary will do the better work. The McKittrick and Coalinga fields offer two types for illustration. The first 1000 ft. of the formation in the McKittrick field includes many granite boulders. Therefore the standard rig is best. In the Coalinga field, however, the best progress is made by drilling the first 2000 ft. with rotary and then changing to the standard. The Creme Petroleum Co., on Sec. 30, T. 20. R. 15, Coalinga field, put down the first 2020 ft. of its well No. 1 with a rotary drill in 35 days. At 2000 ft. a hard formation was encountered and five days were consumed in penetrating 20 ft. of it. The rotary was then moved to a new site and well No. 2 begun. A standard rig was set up to complete No. 1, and this drilled through the hard ground at the rate of 20 ft. per day. A combination standard-rotary drilling rig is now being evolved, which when perfected will consist of both types of drill, so arranged that one may be interchanged with the other with little loss of time. At present there are combination rigs in use, but much valuable time is lost in rigging up for the cable-tools. With the advent of electricity throughout the California oilfields and the perfection of the motor, drilling will hereafter be done largely by that power. Electricity is being successfully used in drilling in the East. Aside from mechanical advantages, it will do away with the cost of fuel and water.

The size of hole to be drilled in starting a well, depends entirely upon the depth to which the well is to be sunk. In a field where the depth to the petroliferous formation is known, a hole of a diameter consistent with that depth is started, and the well can be drilled at a minimum cost. But in drilling in an unexplored field it is safest, and generally the most economical eventually, to start with the

largest size casing, maintaining that size to as great a depth as possible before reducing to the next smaller size. This method permits of driving a well to the greatest possible depth. It has become a very important feature in modern oil-well drilling to shut out all water above the oil-sand. Formerly this was not done, with the baneful result that certain of the older fields today find their oil-wells 'going to water', their oil-sands impregnated to a considerable, and expensive degree with water. Such a condition of affairs will not only ruin developed property, but also render adjacent undeveloped oil land practically unfit to be drilled. Cementing off the water in a well is an expert operation which consists of forcing from a few tons up to as much as 25 tons of concrete firmly about the lower casing, inside and out, at the base of the water sand, and above the oil-sand. The concrete is allowed to set for three weeks before it is drilled through with a smaller size bit. The oil-sand may then be safely entered, and drilled, with all water above completely shut off. The final joint of casing is 'landed,' superfluous casing is removed and saved, all of the casing within the oil-sand is perforated, and the well is ready for the pump.

The following figures may be taken as making up the absolute first cost in the preparation to drill by means of a standard drilling rig.

COST OF RIG

Lumber for rig	$720	
Construction	180	
Cartage	150	
Rig irons	750	
Total		$1,800

BOILER, ENGINE, AND FITTINGS

Boiler, 40 hp	$450	
Engine	330	
Fittings	350	
Total		1,130

TOOLS

Drills, pulleys, accessories		1,600

CABLE LINE, ETC.

Manila line, 2⅛ in., 1500 ft	$400	
Sand line, wire cable, 9/16 in., 2000 ft.	80	
Cable, ⅞ in.	430	
Total		910
Total cost of materials		$5,440

The above figures must be taken into account before drilling can be commenced. In planning to drill, say 2000 ft., casing should be provided as follows:

CASING

300 ft., 13½ in.	$900	
1,000 ft., 11⅝ in.	2,000	
1,600 ft., 9⅝ in.	2,800	
2,000 ft., 7⅝ in.	2,000	
Total		$7,700
In many cases it will be necessary to shut off water; the total cost of which is		600
Total casing and cementing	$8,300	$8,300
Total cost material		$13,740

Of the above casing, there may be withdrawn and saved

Ft.	Size, inches.	Value.
300	13½	$900
1,000	11⅝	2,000
1,500	7⅝	1,500
Total		$4,400

The cost of the well may be credited this full amount if a second well is contemplated and it is found that this casing can be used to advantage therein. For a complete estimate of the cost of the 2000-ft. well, there must be added to the original cost of material, the cost of labor, fuel, and water. These three items depend upon the time consumed in drilling the well. In the California fields it takes from 100 to 150 days, and often longer, to drill to a depth of 2000 ft. The latter figure should be used in estimating.

COST OF LABOR

Two drillers per day	$16	
Two tool dressers	8	
Roustabout and team	7	
Total labor per day		$31

FUEL, WATER, AND LUBRICANTS

Fuel, 10 bbl. crude oil per day	$6.00	
Water	2.50	
Gasoline (for lights), lubricants, etc.	1.50	
Total		$10
Total cost, labor, fuel, water, etc., per day		$41
For 150 days this would amount to		$6,150

The well having been successfully drilled, a pump, tubing, pump rods, etc., must be installed. These will cost:

PUMP AND ACCESSORIES

2,000 ft. of 3-in. tubing	$700	
2,000 ft. of rods	200	
Pump, barrel, etc.	75	
Total		975
The completed well would cost		$20,865

The essential points to be observed in oil-well drilling are: first, determine as nearly as possible what may be expected as to depth, and the character of formation; second, select the drilling rig best adapted to these conditions; third, employ reliable and competent drillers; fourth, cement off all water from the oil-sand.

Zinc dust made in America has only recently come into the market for precipitation from cyanide solutions. The dust from American plants has been manufactured as a by-product in smelting and generally contained too much zinc oxide. The dust imported from Germany is made primarily for use in the dying industry and every effort is made to keep it free from oxide. A small amount of lead is helpful rather than the reverse. Recent sales have been with a guarantee of 92% metallic zinc. The oxide present not only reduces the efficiency of the material and adds to the cost, but occupies valuable space in precipitation presses.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Concentration of Slime

The Editor:

Sir—In the first part of E. A. Sperry's paper on the above subject (*Mining and Scientific Press*, August 6, 1910) he devotes considerable space to the different machines in use for pulverizing ore, and their action, and makes a few remarks on the products. As he says, rolls exemplify pressure action, and stamps impact, while pressure-impact is utilized in Huntington and Griffin mills. A number of the former machines are in use here, crushing the soft oxidized ores. They deal with up to 40 tons each daily, very effectively. As to the Griffin, the South Kalgurli, Perseverance, and Great Boulder mills had 4, 16, and 13 of these, respectively, and from the two former mills they have been discarded in favor of ball-mills, while additions to the latter mill are made by installing ball-mills. The Griffin works by pressure-impact, as ore in the mill is found to have a sharp fracture. Dynamite, which finds its way into the mill, explodes violently, generally breaking the pan and suggesting impact. If the mill runs empty, the muller bangs hard on the die ring, and often the spindle breaks. The Griffin product is fine, and up to 70% will pass 150 mesh, being crushed through a 15-mesh screen. These mills are rather costly to run, and are not favored generally.

In describing pressure-torsion machines, Mr. Sperry does not mention the grinding-pan, which no doubt comes under this head. The shoes on the muller-plate of the pan press heavily on the dies, and as they are revolved, a dragging or twisting motion results, the ore particles being crushed by pressure and dragging or twisting set up. The pan is a good grinding machine, and with feed of which only 45% will pass 150 mesh, 85 will pass the same screen after grinding. About 75 five-foot and 19 eight-foot pans are in use on this field, most of them grinding roasted ore, the balance working in series with tube-mills on raw ore.

The tube-mill is probably the best example of impact-grinding. I understand the action of this mill to be one in which the pebbles are carried almost to the top of the mill, and fall in a shower to the bottom, striking other pebbles at the bottom, particles of ore being crushed by the impact. A tremendous amount has been written on the tube-mill, but I have never seen details of a microscopical examination of the slime particles, whether they show a sharp fracture or otherwise. Of course, a great number of pebbles are simply carried up a certain distance, and then slide back again, or roll over one another to the bottom. Pebbles doing this, would grind the ore more or less. In 1904, the Krupps in Germany made a number of experiments on the action of the tube-mill, these being described by H. Fischer in several technical journals soon afterward. Photographs were taken of the pebbles in action in a mill made for the purpose, and these showed the impact action quite clearly. It would seem that the plain type of liners for the tube are not as good as the corrugated or rough type mostly used now, for the reason that the latter toss the pebbles about more, giving more chance for the impact of one pebble against another, while the smooth liner does not tend to carry them up far, irrespective of centrifugal force.

Where I do not agree with Mr. Sperry, is in regard to the ball-mill. He said: "The ball-mill is a modification of the tube-mill with the substitution of steel balls for pebbles, and steel lining in place of the silex brick. It is designed for dry grinding, and is used extensively in cement manufacture." It is doubtful whether the Krupp ball-mill, which seems to be the most efficient of all the ball-mills,

Balls, Stone, and Pieces of Steel From Ball-Mill.

Note Rounded Shapes and Especially the Perfect Roundness Maintained by the Balls While Wearing Down.

is used anywhere with greater efficiency than it is in Kalgoorlie. There are here at work 27 No. 5 size, which crush up to 45 tons each per day, and 17 No. 8 size, which crush up to 90 tons each. About 45% of the product from a 25-mesh screen on the mills will pass 150-mesh. Now, I fail to see how the ball-mill is a modification of the tube in any way. According to size, the Krupp mill is charged with 1 or 2 tons of steel balls, and revolves at 21 to 25—in one case 24—revolutions per minute. The ore, crushed by the balls, passes through the perforated grinding-plates, and is screened by the coarse or inside punched screens, the oversize being automatically returned to the interior of the mill, while what passes the inside screen is screened by the outside or fine-wire screens, the oversize also being returned to the mill. When the ore is ground fine enough, it is at once passed out of the mill. The working of the mill is ingenious, to say the least. The grinding action of the balls is not due to impact. The only impact that might take place is when the balls drop from one grinding plate to another, a distance of 4 inches in a new mill. The action of the balls is one of pure rolling, grinding, and abrasion, the balls being lifted up level with the mill shaft or axle, and then simply rolling back, tumbling over one another, rubbing and grinding away the ore between them. This is not mere supposition, but fact, as I have actually seen the action. At the Associated mill there are four No. 5 Krupp mills crushing oxidized ore, which contains 5% moisture. Very coarse screens are used on this, as the fine-

screens, 25-mesh, would be clogged. In crushing this ore no dust is made, so by the aid of a portable electric light, placed well down in the feed hopper, the balls can be seen working. Repeated observations show that the balls and ore are carried up about level with the mill shaft, and having reached this point, start to roll back, and the whole 1200 lb. of balls (light balls being used on this soft ore) roll and tumble about, grinding the ore by abrasion. It is a most interesting sight, fully proving that there is no impact grinding. To further prove this, it is only necessary to take note of the ore in the mill when it is stopped for repairs. Down to the finest particle, it is round and smooth, just as if water-worn from a river, where stones are quite round from rolling. Pieces of drill steel from the mine are fed in at times, and these become rounded in the mill, although they hinder the good work of the balls to some extent. The Krupp mill works either wet or dry, but is especially efficient as a dry crusher. To support my theory, I enclose a picture showing the perfectly round form the balls keep in wearing from full size to the smallest, the rounded pieces of ore and steel, the latter originally hexagonal, and two pieces of plate which do not add to the grinding efficiency of the mill. I have a paper on 'Ball-Mill Practice' in preparation, which I hope to publish in your journal, and which will be of interest to millmen generally.

M. W. von Bernewitz.

Kalgoorlie, Western Australia, October 10.

Are Engineers Honest?

The Editor:

Sir—In reviewing a back number of the *Mining and Scientific Press*, I find an article entitled 'Are Engineers Honest?' Most of them are. And there are some who are so honest that they would not accept a share of the promoter's commission unless the promoter mentioned it first. There are others who would not permit a sale to go through unless they did get a division of the commission. I have suffered from both. A certain property in Nevada had been offered to prospective investors in Iowa. They sent an independent engineer to make an examination. The measurable ore in sight consisted of about 30,000 tons of $12 ore. In a surface deposit, which had been thoroughly prospected, was available something like 150,000 tons of $6 ore. The engineer declined the property on the ground that the ore did not come up to the figures in the original report. His only contention was that the surface deposit was not an asset and that "nothing that nature has exposed can be regarded as ore in sight." Ore blocked out it was not; but 'ore in sight' it certainly was. However, later a company was organized to operate this same property and the gentleman in question became a member of the directory, as well as consulting engineer for the company, and every one of the prospective investors in Iowa received a recommendation from him to purchase the stock at a figure that made the property cost the stockholders more than twice the price at which I had offered it—notwithstanding that in the meantime not a dollar's worth of work had been done and the conditions were the same as when the engineer made his first report. Was this man honest?

A property in California was offered to prospective buyers at Pittsburg. The vein was five feet wide, but contained about two feet of ore that was of too low grade to warrant sending it to the mill. This two feet had always been discarded and thrown over the dump. In the estimate of ore reserves given in the original report this fact was particularly mentioned and the tonnage based entirely on the three feet of profitable material. The independent engineer who examined the property took his samples entirely across the vein, notwithstanding that he was furnished with a copy of the original report. Naturally his results fell well below the original estimate. In contrast with the gentleman mentioned above, I believe this engineer was honest. But his discrimination was bad. He should not have included two feet of worthless material in his sampling.

A certain engineer with an established reputation in South Africa, Australia, and South America recently examined a tungsten property in the Southwest. This was an extensive surface deposit and had been favorably reported on by one of the best authorities on rare metals in the United States. The gentleman from South Africa looked at this deposit from a distance; he did not enter any of the workings, and did not even inspect the vein closer than 500 yards away. He returned to his principals and condemned the property on the ground that it did not 'go down.' Now, what would happen to this tungsten if it should go down? It would most certainly develop a sulphide and in that case it would be almost impossible to market it at all, as the elimination of sulphur from tungsten concentrates has not yet been successfully accomplished, and the German buyers who were figuring on purchasing this deposit stated emphatically that what they desired was a large surface deposit and that the concentrate must be free from sulphur. This engineer had previously stated to me that he had paid no attention to the rare metals and was not familiar with them. That being the case, he had no business to accept the commission to examine a tungsten deposit. Was this engineer honest?

Among the twelve most familiar names of mining engineers in the United States is a gentleman who operates quite extensively in the Southwest. This engineer drove eighteen miles from the railroad to look at a copper property, spent less than two hours on the ground, returned to the railroad, 'turned down' the property, and received a fee of $100 per day and expenses for his 'examination.' About three months later he offered to take an option on the property from the owner and stated that he could sell it in New York 'at a big figure.' Was this man honest? How long will investors continue to pay for such service? No profession today requires more integrity, better judgment, or more careful work than that of the mining engineer, and it is time there should be an end to 'examinations' of the character mentioned above. George F. Goerner.

El Paso, Texas, November 30.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Costs are usually much higher when actually kept than when 'estimated.' At one property recently, the superintendent 'estimated' the mining cost at $1 per ton and the milling at 85c. Several months careful record showed the first to be really $3.20 and the second $1.10.

Switches may be placed in trolley wires so arranged as to be thrown by the same lever that opens or closes the switch in the track. Such a device has been in use for some time at the Cresson mine in the Cripple Creek district of Colorado and works satisfactorily. It obviates all slipping of the trolley and saves time and labor.

Publications of the U. S. Bureau of Mines may be obtained free upon application to the Director, U. S. Bureau of Mines, Washington, D. C. Two bulletins have so far been issued, but the new Bureau also distributes certain of the bulletins of the U. S. Geological Survey based upon work done by the Technological Division of that organization prior to July 1, 1910.

In caisons, the limit of practical working pressure is about three atmospheres, or about 45 pounds per square inch. At this pressure work can be performed at a depth of approximately 100 ft. Not many men can work under such conditions, and there is no doubt that the lives of caisson workers are shortened by the unnatural pressure on the lungs that such occupation and attendant conditions impose.

Civil Service examinations for various positions in the public service are constantly held in many cities and towns. Details can always be learned by applying to the U. S. Civil Service Commission, Washington, D. C. There is a chronic shortage in male stenographers, and any young man capable of doing good work as a stenographer is reasonably sure of appointment if he pass the examination successfully.

Mill saving can only be estimated approximately by means of tailing samples, for the reason that at best no proper allowance is made for the value of dissolved metals. Frequently also much of the metal is so finely divided that it floats past the sampler and is lost. There are many concentrating mills where saving is supposed to be 90% but is really 65 or less, as has been shown where sale of concentrate was checked against proper sampling of the mill-feed.

Carbonas are irregular tin deposits occurring in granite and found only in West Cornwall. They are described by J. H. Collins as "silicious, and generally highly chorlaceous segregations containing enough tin to be worth working." They are usually slightly connected with lodes. Those formerly worked were all discovered by accident, and possibly many others remain undiscovered. Some, he thinks, may have originated in a cavity or vug, which gradually became enlarged by simultaneous solution and precipitation.

Potash salts are mined in Germany to the amount of 6,000,000 tons annually. Exports amount to $35,000,000 in value per year, and the potash mines are coming to be regarded as one of the country's greatest natural resources. The Kali Syndicate controls 60 mines and it is reported that 40 more are to be opened, thereby increasing the output 100%. Germany has at present a practical monopoly of known potash deposits. Hanover is the recognized centre of the district, though most of the mines are in the vicinity of the Harz mountains.

Decantation methods of cyanidation almost always necessitate crushing in solution, as otherwise the pulp must be de-watered before cyanide solution can be added. A few years ago when amalgamation was more general, decantation was common. Running solution over the plates, however, in time ruins them, and for these and other reasons it is becoming common, particularly where silver is present in the ore, to do away with the amalgamation, to crush fine, and to depend upon filters. New plants are quite generally built on these lines, in the United States particularly, and old ones are being remodeled.

Dredges may be counted toward annual labor and for patent improvements under certain conditions. For example, where it can be satisfactorily shown that an area embraced in a placer location, or a group of locations held in common, contains deposits of such a character and extent as to permit them to be more economically worked by means of a mining dredge than by any other means; that the owner of the claim or group has in good faith purchased, and actually placed in good working order thereon, a dredge, for the exclusive purpose of working such deposit, and that the dredge has not been used as the basis for patent for any other area, it is entitled to be regarded as a mining improvement so far as that particular claim or group is concerned, and to have its cost accredited thereto. Under such circumstances the value of the dredge can be applied, for both patent purposes and annual assessment work. Necessary remodeling and improvements on the dredge if of a permanent nature, should also answer as assessment work if the dredge itself conforms to the foregoing requirements. The operation of the dredge on one of the claims will hardly answer for assessment work for the group. The Land Office has decided that work on the lower end of a placer deposit started so as to work upstream and avoid the necessity of rehandling the tailing, facilitates the extraction of mineral from the entire group of claims only in a remote sense, and that the value of such work done on one claim of a group can not be accredited to an adjoining claim as an improvement for patent purposes. While the courts are usually a little more lenient in their rulings on the character of assessment work required, yet the same general principles apply.

Special Correspondence

BULAWAYO, SOUTHERN RHODESIA

Gold Production of Southern Rhodesia. — Output of Other Metals. — Globe & Phoenix Co.—Monomotapa Mines.

The mineral output of Southern Rhodesia has been steadily diminishing for some months past, and the return just announced in the September operations constitutes a further decline in production. The total value for September was £196,626 as compared with £216,562 for the month of August. Of the total value recovered gold accounts for £178,950 or £12,473 less than in August. The gold output for September 1910 is found to be £34,299 below that of September 1909. This marked decline, although it may cause shareholders in Rhodesian companies some anxiety, causes no alarm in the country itself. The suspension of normal milling operations at the Globe & Phoenix mine, which is by far the largest producer in the country, and the shutting down of numerous small mills in order to push development, account for the decline in production. The large amount of development being carried out in nearly every district of Matabeleland and Mashonaland foreshadows an early expansion of productive operations, and in so far as the Globe & Phoenix mine is concerned it is satisfactory to note that the mill is now running at full capacity again. During September the company crushed 601 tons only, but secured a yield from this of 1909 oz. fine gold. In order to compensate for the low outputs announced during the period of repair work, the directors have given instructions to mill ore of high grade during the remaining months of the year. The values of the minerals, other than gold, produced during August and September are given below:

	September.	August.
Silver	£1,758	£ 1,985
Lead	711	701
Chrome iron	3,050	13,875
Copper	9	218
Asbestos	250	300
Coal	7,898	8,060

From this it will be seen that the decline in the production of chrome iron was, apart from the decrease in the gold output, the most unsatisfactory feature of last month's output. The decrease was solely due to shortage of labor and to a hitch in the shipping arrangements at the port of Beira in Portuguese East Africa.——A sensation has been caused in Salisbury by the arrest of Dracopoulos & Coutlis, the late owners of the Colossus mine. They are charged with contravening that section of the mining ordinance which relates to 'salting.' Some few weeks ago N. A. Arnold of Arnold & Co., of Salisbury, purchased the mine from the two defendants for the sum of about £25,000. Shortly after the transfer of the mine there were rumors that the property was not all it was supposed to be, and these reports led to the arrest of Coutlis, near Salisbury. Dracopoulos was arrested at Cape Town a day or two later. The incident is regrettable, as in any case it cannot fail to give an unfavorable impression to European investors, and it is to be hoped that in all cases in future in which a conviction is secured against persons breaking this section of the mining law an exemplary sentence will be passed. ——A report has just been issued by the Globe & Phoenix company in which it is stated that at the end of June last the estimated payable ore reserves amounted to 174,788 tons, of an estimated average value of 32.259 dwt. per ton, the gross value of which amounts to £1,184,097, as compared with £1,124,878 at the end of last year, and £1,045,151 at the end of September 1909. An encouraging feature is that in the lowest workings the ore is of good grade over a substantial stoping width. On account of repairs to the main shaft the ore milled during the six months ended with June last amounted to only 23,535 tons. The output of gold was £183,058, while the profit realized was £137,678. By reason of the small tonnage milled the working costs were abnormally high, being 37s. 3d. per ton milled. It is interesting to note that on the fifteenth level, above the dike, the east reef and combined reefs show a value of 5 oz. 5½ dwt. per ton over a width of 41.6 in., for a length of 1025 ft. of driving. On the sixteenth level, below the dike, the total length driven on these reefs is 725 ft., and the ore averages 131.9 dwt. over 39.3 in., the north drift being still in high-grade ore.——Sir Thomas Cullinan, of Premier Diamond mine fame, has been visiting Mashonaland in connection with his Monomotapa properties in the Kaiser Wilhelm goldfield. For three years development has been proceeding on these mines, and a reduction plant is now being erected there. In about six months it is hoped to commence productive operations on a basis of 10,000 tons per month. It is reported that on one of the properties there is a body of ore about 300 ft. wide, of low grade. Sir Thomas hopes to work this at a profit.

JOHANNESBURG, TRANSVAAL

The New Kleinfontein Mine.—Bantjes Consolidated.—The City Deep. —Tin Mining in the Transvaal.

The New Kleinfontein mine on the East Rand, for some years past, has been one of the most consistent producers and dividend payers at work on the Main Reef series, and much disappointment has been occasioned by the recent decline in profits and by the fall in the grade of the ore reserves. The grade of ore stamped for the month of September was affected by a subsidence in the old stope above the auxiliary east shaft which resulted in a reduced

Premier Diamond Mine.

tonnage for that part of the mine. But the trouble at the New Kleinfontein is evidently of a more permanent nature than one would gather from this statement which has been issued by the board of directors. It is officially admitted that recent developments have been below the average and that in consequence of this the directors "have decided temporarily to reduce the grade," and there will be a reduction in profits to £20,000 per month. Last year the company's profits averaged £25,000 per month, so that the dividends for the time being are likely to be affected detrimentally. At the end of 1909 the average assay-value of the ore reserves was given at 7½ dwt. per ton, but these have since declined to 7 dwt. As against this depreciation it is important to note that the milling equipment is being increased, and it is expected that the company will be crushing 50,000 tons or more per month by June of next year, instead of 40,000 tons as at present. This increase in the scale of working should bring about an appreciable reduction in working costs which are now about 16s. 6d. per ton milled, and it is trusted that the economies resulting from milling on a larger scale will counteract the fall in the grade of ore crushed.——The disappointing returns from the Bantjes Consolidated company during the first few weeks of crushing had a most depressing influence on the Kaffir market. Pessimistic rumors were afloat regarding the mine, and these were strengthened by the unsatisfactory results which were announced by the Vogelstruis Consolidated Deep Co., results which led to the closing down of the mine which adjoins

the Bantjes to the west. It is not to be expected that in the first few days of milling, a mine will give any indication of its normal producing ability, since there is always a certain amount of gold in circulation in the cyanide plant and a considerable amount is absorbed in setting the plates. A later announcement, however, has re-established confidence in the property, and from the satisfactory returns last published it is clear that the mine is going to justify the high opinions formed of it before milling operations commenced.——A further disappointment has been caused by the announcement that the City Deep, which was to commence milling this month, will not declare any returns until early next year, although stamps are about to begin dropping. No doubt this decision of the directors has been to some extent determined by the manner in which the early and abnormal returns of the Bantjes company, which also is under 'Corner House' control, have been magnified out of all proportion to their actual significance and value. In the first instance the reduction works of the City Deep will have a capacity of 60,000 to 65,000 tons per month, and it stands to reason that such equipment cannot be got into normal order in a few weeks.——There is something in the nature of a tin boom in the Transvaal at the present moment. The investment of a large sum of money in the Rooiberg Minerals Development Co. by such an influential and wealthy corporation as the Anglo-French Exploration Co., coupled with the good results obtained in the development of the mine, and also the profits being earned at Zaaiplaats and other mines in the Waterberg district of the Transvaal, have directed the attention of investors to the possibilities of tin mining in the Transvaal. In the eastern part of the Rooiberg mine some rich ore has been opened, and this quite apart from the network of lodes which constitutes the main section of the Rooiberg mine.

JARBIDGE, NEVADA

Good Progress in Development.—Many Leases.—Pavlak Mill.—A New Wagon-Road From the South.

There is greater activity in the camp now than ever before and the future of the district looks bright. A mill is being built, two new roads are being constructed, and prospectors are finding ore in many places. The Pavlak Co. was the first to begin development and it is the first to purchase and erect a mill. Contracts have been made with the Chalmers & Williams Co. for a cyanide plant which is to be placed in operation as soon as possible. Most of the material for this mill is now on the way to the camp, and 10 or 12 freight teams are arriving every day with lumber and machinery. W. T. Morgan is superintending the grading of the millsite. The timbers for the mill building will be hewed from native trees, found on the ridge between the Jarbidge river and Bear creek; the logs are being brought down to the river bottom. The mill is to be built on the bank of the Jarbidge river, at the mouth of the adit, and the solution-tanks will be placed on a bench 80 ft. above the mill-floor. Sidney Coburn, superintendent for the Pavlak company, has done much for the prospector and the camp in general; he has employed local help and patronized the local stores where possible. He is now giving work to men who have been prospecting all summer. The mill is to treat ore from other mines, though the company is opening up so much ore on its own ground that it is not probable that it can handle a large tonnage of custom ore.——The 4-M lease is driving north and south on the vein at the 50-ft. level, and is accumulating a lot of milling ore.——The Riddle-Corrigan lease has the vein opened by two adit levels, and has considerable ore in sight which runs from $12 to $16 per ton.——The Curley lease has driven 80 ft. on the vein and has ore that pans well.——The 'Ham And' lease, on Pavlak ground, has an 80-ft. adit on the Taft vein, which parallels the Pavlak vein. The ore thus opened pans $14 to $65 per ton. This lease is in the hands of Albert McCloy, Cash Andrews, and C. E. Murry. They have started a cross-cut that will tap the orebody 65 ft. below the first adit, and enable them to deliver their ore on the wagon-road.——The Amazon-Rainbow company, for which Theodore Parks is superintendant, has driven an adit 90 ft. on the Amazon lode, in which is a showing of good ore. This adit will intersect the main Pavlak vein in the next 50 ft. This company will be able to supply ore to the new mill.——The Good Luck mine, also in charge of Mr. Parks, has driven an adit about 100 ft. and has some high-grade ore. The tunnel heading is nearly under the surface outcrop and Mr. Parks expects soon to cross-cut the vein.——The Clark-Fletcher lease on the North Star vein has cross-cut from the lower adit a shoot of rich ore and is raising on the vein.——James Duncan has bonded the Guess, Guess Fraction, and Buster Brown claims, for $50,000, to Featherstone and associates, who are preparing for work this winter.——Theodore Parks has bought the interest of Pete Garner in the Last Chance No. 1 and No. 2 claims, south of the Bourne mine. He expects soon to begin the development of this property.——McCormack and partners have bonded the Sugar group of four claims in the Fourth Crater for $50,000, to Jack Griffith, who represents Butte capitalists.——Lige Fletcher and others of Boise have started a cross-cut on their Miss Mac group, northeast of the Bourne. This property is east of the quartzite dike and some of the surface dirt pans well in free gold.——The Free Fissure Gold Co. has opened three veins on the east slope of Jumbo peak and is finding good ore, including high-grade specimens.——Work in the Jack Creek Crater, three miles southeast of Jarbidge, on the property of the Coeur d'Alene-Jarbidge Gold Mining Co., is progressing well and with good results. The property is favorably situated for cheap and quick development. Present work is upon two ore-shoots, containing some free gold. The company has made preparation for the work and six or eight men are to be employed this winter.——The Elko county commissioners have undertaken to build a new wagon-road into camp from the south, connecting with the Deeth road at Charleston, which will give an outlet to the Western Pacific railway at Deeth, affording cheaper freight rates and reducing the price of merchandise in this camp.——A company has been organized with a capital of $10,000 to build this road, the county guaranteeing to take up the stock in one year at an advance of 8%. A force of men, 20 teams with scrapers and two road machines are at work on the new road, trying to have it ready for winter travel.——The Elko County road to Jarbidge is causing the Twin Falls merchants to have a new road surveyed out of the camp which will give an easy grade and avoid the bad points on the old road, besides making the distance several miles shorter. Effort is being made to finish this road as soon as possible in order to have it ready for the hauling of heavy machinery for the Pavlak mill.——The next great need of the camp is telephone connection with Elko and Twin Falls. The Elko Telephone Co. has the money ready to build such a line and has asked for bids to extend its line from Gold Creek to Jarbidge.

GOLDFIELD, NEVADA

Affairs of the Goldfield Consolidated.—Litigation.—The Florence Orebodies.—General District News.

The regular quarterly meeting of directors of the Goldfield Consolidated Mines Co., announced for December 1, at the Waldorf-Astoria hotel, New York, will have been held before this is in print. John H. Mackenzie, director, consulting engineer, and formerly general manager for the company, came to Goldfield last week to inspect the mines and mill, and left for the East in company with A. H. Howe, secretary and treasurer, and J. R. Finlay, general manager. At Reno they were joined by the president, George Wingfield, and it is said that W. C. Raiston, of San Francisco, another director, proceeded to New York with them. In the absence of Mr. Finlay the company's operations are in charge of J. F. Thorne, assistant general manager. Mr. Finlay's report to the board of directors concerning the results of recent work on the 1000-ft. level of the Clermont mine will be looked for with much interest.

The new ore-shoot being followed at this depth thus far has averaged about $65 per ton, and the deposit is apparently of great magnitude. It is believed to be identical with the famous '403' stopes of the adjoining Mohawk. This rich ore is readily separated from the rest and is used with low-grade ore to maintain the desired average in mill-heads; or is sometimes shipped to smelters for separate treatment. On the 750-ft. level of the Clermont there remains a good deal of ore of this character as well as at other points, particularly in the Mohawk and Combination. The largest tonnage of ore now comes from the Clermont, which has supplanted the Mohawk as the leading producer of the five mines. The product of the Clermont also leads the other mines in grade of ore.——Suit has been filed against the Consolidated company by the Frances-Mohawk Mining Co. to recover the sum of $254,800, which the latter alleges is 77½% of the amount of rich ore stolen from its lease on the Mohawk and from the Hays-Monnette lease, during the life of those bonanza leases, and which it is claimed was recovered by the Consolidated company. A part of the amount represents a claim assigned by the Hays-Monnette people to the Frances-Mohawk company. The complaint alleges that ore valued at $500,000 was stolen by miners and others from the Frances-Mohawk lease, and that $300,000 worth of high-grade ore was taken from the Hays-Monnette lease; but that the Consolidated recovered only $334,000 worth of the stolen ore. The Consolidated and Frances-Mohawk have been involved in litigation for over two years, several suits being still pending in the courts of this State. ——The Florence Goldfield company is to drive laterals from the 600-ft. station to explore several orebodies that have been highly productive on and above the 500-ft. level, and the management is convinced that this work will result in opening ore equal to that mined so profitably by lessees. During the past year the work on the Florence has been largely devoted to cleaning up the old lease workings, and connecting the various workings in order that mining may be carried on more effectively. All the main drifts, stopes, and levels are now connected with the main shaft, chiefly on the 350 and 500-ft. levels, and it is said there is a large tonnage of ore in sight. The mill has been making a profit from the lowest-grade ore treated. Some of the best ore is being taken from the stopes opened by the north drift on the 350-ft. level. Good ore is exposed on the 500-ft. level, between the main shaft and the workings of the old Engineers' lease. A winze sunk 60 ft. below the 500-ft. level on the Rogers-Syndicate lease, has also resulted in opening good ore. The three leases yielded a large tonnage of rich ore and paid good profits to the operators, who, under the terms of the leases, were prohibited from removing ore sampling under $35 per ton. In the earlier operations ore worth less than $70 per ton was not marketable by lessees.——Ore of good grade is being sent to the sampler from the Red Top Extension, being worked under lease by some of the stockholders of the holding company. An ore-shoot was exposed by raising 68 ft. above the 500-ft. level, 100 ft. from the shaft. The ore is said to be 6 ft. wide and assays an average of $40 per ton.——Small shipments have been made lately from the Goldfield Annex lease on the Polverde claim of the Jumbo Extension, adjoining the Clermont. Some ore was taken from the 800-ft. level last year, but the shoot was lost and the shaft continued to a depth of 1100 ft. Failing to find ore at the deeper level, work was again commenced on the 800-ft. level with the result that the lost ore-shoot was recovered in a cross vein, thought to be an offshoot of the Clermont.——Good ore is in sight on the 250-ft. level of the Knickerbocker-Wheeler lease on the Spearhead, and the vein has been opened on the 350-ft. level. This vein is unlike anything opened in the district, the mineral content of the ore being gold, silver, and copper, running heavy in iron and copper sulphide.——Driving continues on the 1170-ft. level of the Grizzly Bear lease on Consolidated ground, a short distance south of the Clermont, but only low-grade ore has been exposed.——In the southern part of the district the Yellow Tiger has work in progress on the 700-ft. level.——On the 450-ft. level from the Victor shaft of the C. O. D. Consolidated there are indications that the ore-shoot displaced by a fault on the 300-ft. level has been found, and lessees are developing at 600-ft. depth on the Gold Bar claim.

ALASKA

High-Grade Ore Near Fairbanks.—Successful Leasing.— Winter Work on Placers.

With the last clean-up of ore taken from the Crawford lease on the Rhoads-Hall vein, it was found by figures given by the banks that the 3-stamp test mill at Fairbanks has pounded out during its brief existence almost $40,000. This mill has been in operation about a year and a half, and, except for the ore mentioned above, has worked exclusively on small lots for test purposes only. The ore taken from the Rhoads-Hall property will average about $150 per ton in free gold. A clean-up of a 9-ton lot showed $170 per ton, while one lot of 17 tons yielded $178 per ton. Concentrate from the ore assayed $1000 per ton; a doré button of ¼ oz. being smelted from 5 lb. of concentrate. ——Fairbanks creek has been the scene of much activity in prospecting lately. August Hess reports finding a rich vein a few days ago opposite placer claim No. 13 Above Discovery. Little work has been done, but the rock shows considerable free gold. A quarter interest in the group of eight claims owned by Cook Bros. & Lundblad was recently taken over by L. M. Drury and Paul Hopkins. Mr. Hopkins is the assayer for the Washington-Alaska bank, and Mr. Drury is proprietor of the Tanana assay office. This group of claims is on the left limit of Fairbanks creek, opposite creek claims 11 and 12 Above Discovery. Four samples from one of the claims of this group assayed $124, $93, $53, and $206, respectively. The last sample was from the bottom of the shaft. Development work will be carried on all winter and a small test shipment will be sent in soon. The veins have a good width and excellent walls.——Two leases have been let on Alois Frederick's ground near the head of Vault creek. Ernest Peterson has a block of ground above the railroad track, and Glazier, Crockett & Polson have a lease directly below. Buildings are being erected and development will be carried on all winter. Machine-drills have been ordered. It was found lately that the railroad track, where it cuts across the vein, is ballasted with rock worth $100 or more per ton.—— E. W. Herschberger, who originally had a lease on the upper end of the Frederick's vein, has just run a 6-ton lot of ore at the local mill. The clean-up showed the ore to run $60 per ton in free gold.——Across Vault creek and seemingly on the extension of the Frederick's vein, Hoel Bros. and Johnson & Witman are preparing for work this winter. Buildings are being erected and supplies hauled. Sam Moe and partners recently sold their property on Eva creek for $8000. Eva creek is a tributary of Ester and is thought by many to have contributed most of the gold to the famous Ester creek. Among the small lots of ore awaiting treatment at the local mill are several tons from the Anderson property on Birch hill, a few miles from town. This is from a 5-ft. vein. A test run on ore from the 5-ft. vein on Cleary hill, belonging to W. McDonough and partners, showed $30 per ton in free gold. The concentrate has not been assayed as yet.

The adit being driven on the Spaulding vein from the lower end-line shows it to be widening into a good ore-shoot. On the upper end, Huddleston Bros. have a lease and have buildings completed. They start work on the 60-ft. shaft sunk by Spaulding & Clough that shows 3 ft. of good ore.——Several tons of rock from the Pioneer quartz claim was run in the local mill last month and returned $70 per ton free gold. Mr. Calvin also put through a small lot from the Jupiter-Mars which is said to have shown still better results. Efforts have been made lately to compromise the differences between the Butler-Petree people and the owners of the Rex, the adjoining property. These efforts have failed, however, and a suit to quiet title will undoubtedly be brought. Both properties are prom-

ising, considerable work having been done on the Butler-Petree, where a 160-ft. incline shaft shows a wide vein the whole depth.

The custom mill at Chena, eight miles below Fairbanks, is nearing completion. Many offerings of ore have already been made, and when the big leases on the Spaulding-Clough property and the Frederick's get started the mill should easily be kept busy. Mr. Cunningham is in charge. ——Some pay has been found on the left limit of Goldstream, and two other creeks have developed bench pay. On Dome creek, pay has been found high on the right limit opposite No. 8 Below. A continuation of the Ester paystreak has also been recently found by a drill. The pay seems to run through the right limit of Ester, where the benches have always been wet. The new ground is also wet, but pannings from the drill-hole show a value of $17 per square foot of bedrock, enough to insure a handsome profit if the ground is uniform.——The river is now closed for navigation, the bulletin board reading: "The last boat will be a four-horse stage, leaving Thursdays and Sundays."

NEW YORK

Prices on a Low Level.— Railroad Securities. — No More Speculating Directors.—Copper Interests Co-Operate.— Incentive for Copper Merger.—No Real Curtailment.—Copper Dividends.— Utah Consolidated & I. S. & R.

The event of the week in financial circles was the collapse of the attempted bull campaign reputed to have been backed by the Morgan interests. Prices were carried well toward the low levels of the year. The railways are going through a period of transition. The new element in the transportation problem is the public, represented in commissions, and commerce courts. The effect in the financial market will be to remove the railroad securities from the field of speculation and put them in the investment class. Speculating directors are to be eliminated and in the future boards will be required to really direct the operation of the roads.——The Government's suit against the Sugar Trust has revived the feeling that the Supreme Court is certain to decide against the corporations in the Standard Oil and Tobacco Trust cases. Until some way is found out of the present entanglement of affairs, broad market operations are not to be expected. This is clearly demonstrated in the copper situation. The co-operation between the various producers is frank and apparently complete. Most of the leaders got together as guests of John D. Ryan at a dinner at Sherry's last week. The copper merger is apparently to await the action of the Supreme Court. If, in the meantime, producers can co-operate and curtail, sell accumulated metal, and strengthen cash reserves, it is so much gained. Just now it is not co-operation or economy of operation that is the incentive for a copper merger. It is to provide the market with a new and popular leader and to create and distribute a billion of new capitalization that is desired.——The forthcoming statement of the Copper Producers Association for the month of November will be awaited with interest. While there is much talk of curtailment, figures from individual properties fail to show great restriction of production. Utah Copper produced in October, 7,582,219 lb. of copper, which is about one-half million pounds more than in September and nearly as much greater than the August output. The production of the Nevada Consolidated in October was 5,250,000 lb., being an increase of about 100,000 over the September output. The Butte output for November is estimated at 23,636,550 lb., as against 22,913,781 for October and 22,990,050 for September. It is hard to see where the curtailment is to become apparent. The regular chain of Guggenheim dividends are being declared. In some cases these dividends are declared and paid four times before ultimately reaching the pocket of the individual shareholders. Nevada Consolidated pays 37½c. per share quarterly; Utah Copper, 75c; Guggenheim Exploration, 2½; Yukon Gold, 10c. per share. ——The special meeting of the A. S. & R. Co. has been called for January 5, 1911, to authorize the issue of $15,000,000 6% convertible bonds, of the American Smelters Securities Co. The conversion privilege gives holders the right to exchange the bonds for the common stock of the A. S. & R. Co. whenever the bonds sell at par or better. The bond issue is underwritten by Kuhn, Loeb & Co., and has been by them divided among the members of a syndicate of the leading banks in the Street. Through the expected conversion of the bonds and common stock the smelting company will ultimately receive the proceeds giving it approximately $15,000,000 additional cash capital. The cash in hand at present is about $12,000,000; ores and metals on hand aggregate in value about $23,000,000. On this basis the cash assets of the company will total about $50,000,000, which just equals the preferred stock liability. The properties of the company and the common stock of the Securities company represent therefore the common stock of the smelting company. The president of the A. S. & R. Co. says in his letter to the stockholders: "This company is now in receipt of ores and bullion from Africa, Australia, South America, Spain, France, Central America, China, and Alaska. As yet it is only feasible to transport Alaskan ores produced on the sea coast, but with the construction of railroads, it is believed that a great mineral production will flow to the smelting and refining plants of this company."——One of the principal events in the copper-share market was the settlement of the suit brought by the North Butte company against the Tuolumne Copper. The compromise was apparently a complete backdown for the North Butte, the net result being that matters stand just as they did before the suit was begun, save that Tuolumne has waived any claim for ore wrongfully extracted by the North Butte. The buying in the shares reflected some accumulation of the stock by North Butte interests, but the decline in the big market which has been drastic throughout the week has caused the issue to ease off and activity to become less marked.——The end of the life of the Utah Consolidated, coming unexpectedly, will be somewhat of a blow to the I. S. & R. Co., whose new plant at Tooele was erected largely to handle the ores of the Utah Consolidated. The aerial tramway which is to carry the ores from the Utah Consolidated to the smelter at Tooele has never been taken over from the builders, though it is said that it is now working satisfactorily. In reference to this situation, the I. S. & R. Co. has issued a statement saying: "Our contract with the Utah Consolidated is at a low rate of toll. When it was seen that Utah Consolidated was not going to maintain the output expected, we made an active canvass and secured other contracts, so that practically from the date of the beginning of operations, the outside tonnage has been as large or larger than the output of the Utah Consolidated and at much better rates."——The Ray Central Copper Co. is in the market with $1,900,000 of the bond issue remaining in the treasury seeking an underwriting; with the bonds there goes an option on 250,000 shares of stock at $1 per share and the active management of the company. The present market in the stock is around 2⅜, so that an option at $1 in strong hands would mean a considerable profit for market operations.——F. L. Underwood has resigned as president of the California-Nevada Copper Co., and has been succeeded by M. N. O'Boyle, of Pittston,

Mineral Creek, Ray, Arizona.

who is one of the large independent anthracite coal operators in Pennsylvania.——The California-Nevada Copper Co. is building a large mill on the Ebner gold property near Juneau, Alaska.——In mining circles an important feature is the growing interest in Porcupine. The camp is said to be very active. The frost has hardened the trails and traffic in and out is heavy. There are many sales reported at big prices, but these deals are said to be made on long-time bonds; however, many cash sales are being made, claims bringing from $1000 to $5000 each. The area of mineralized ground is being widened materially, many claims being staked out in the Reserve to the south.

WASHINGTON, D. C.

Report of Secretary of Interior. — Recommends Appeal of Land Cases to Court.—Recording of Mineral Location Notices. — Leasing Oil Lands.

The report by R. A. Ballinger, Secretary of the Interior, contains many recommendations of interest to mining men. The Secretary urges the prompt passage of House bill 27071 which anthorizes appeal from the final decision of the Department in land cases to the Court of Appeals of the District of Columbia. He also recommends that the famous Alaskan coal land cases be transferred directly to the court without the necessity of a ruling by the Commissioner of the General Land Office, and strongly condemns the present chaotic conditions regarding coal land in Alaska. He recommends legislation requiring that notices of mining locations be recorded in the office of the register and receiver of the land districts; requiring final payment and entry for mineral claims to be made within seven years from date of location, exclusive of any time covered by pending adverse or contest proceedings; and modifications of the placer mineral laws so as to provide that no placer location hereafter made, whether by one or more persons, or an association of persons, shall exceed 40 acres in area. In a general review of the situation regarding mineral lands, he says:

"For nearly forty years the statutes have declared that all valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are to be free and open to exploration and purchase and the lands in which they are found to occupation and purchase by citizens of the United States and those who have declared their intention to become such. Rich deposits of precious metals in the Pacific States and Territories have been discovered and located under these general mining laws and have been operated for many years. Granting defects in the laws, they have accomplished their purpose in causing the mineral resources to be developed and have thus contributed enormously to the wealth of the nation. It is hardly reasonable to believe that any material change will be made in these laws or of the method of disposal of the lode and placer claims of the mineral regions. Here, as in the settlement laws, the Government's liability has had its reward in the material prosperity of the people, and while abuses have existed, they can not be charged so much to the law as to evasions of the law. By the Constitution, Congress is made the steward of the public domain and for its stewardship it is responsible to the people. The executive can move only as directed or authorized by Congress in selling or otherwise disposing of this national estate; therefore all questions relating to a change from the existing status or of policy over this estate resides alone in the legislative branch of the Government, and all popular movements looking to the reformation of our land system must of course be addressed to the Congress. Consequently the movement to conserve the national resources in this national estate of lands—that is, to secure the wisest and most lasting benefit to the nation in their use—is a matter with which Congress must deal. New or amendatory legislation respecting our public lands should be direct, simple, effective, and relate principally to the proper form of disposition of the withdrawn lands—water-power sites, oil lands, coal lands, and rights of way over public lands. The unappropriated public lands of the public-land States and Territories amonnt to about 712,000,000 acres, and, as compared with the private lands in these various States, are a small percentage of the territory thereof, and the Federal Government should not undertake or assume the entire burden of the conservation of the natural resources of the States in which they are situated, for it has been demonstrated that the States are capable of taking care of these questions in a large measure, as is shown by the legislation effectuating these purposes in States like Massachusetts and Washington, at the extremities of our country."

The Secretary directs attention to the recommendations contained in his report for 1909 for coal-land legislation and quotes from an official statement made in 1907, wherein some of the difficulties which would be encountered in the operation of a leasing system are pointed out, and again calls attention to the importance of enacting legislation which would give the Department an effective method of disposition of coal lands, especially in Alaska. He points out that in Alaska it is possible that a leasing system could be adapted to the country with efficiency and with less complication than in the States. In the States the administrative policy is to secure by appraisement and sale of the coal deposits which would accrue to the Government if the deposits were mined on a royalty basis, but this is not possible under existing law in Alaska, where the price is fixed at a flat acreage rate. In regard to oil lands, he says:

"I am in favor of a general leasing system of oil and gas-bearing lands, such a system as will promote legitimate development of this industry, prevent monopoly, and conserve one of the great natural resources of the country. The oil land of the five civilized tribes in Oklahoma is developed on the leasing system, the term of the lease extending as long as oil is found in commercial quantities. The lessee usually pays to the Government for the use of the Indian one-eighth in value of the oil produced as royalty. This system has worked out very satisfactorily and is in use in many of the oil regions of the country where land is held in private ownership and not by the Government. I would apply the leasing system only to areas withdrawn for classification or classified by the Geological Survey. The unknown and unexplored oil lands I would leave open to exploration and location. This would give a reward to the diligent prospector. Even then the surrounding lands could be withdrawn from further location after the prospector had secured his first claims. I recommend that the Government adopt a liberal policy in opening the oil lands in California. The Government ought to support any movement which would reduce the enormous cost of fuel in California. The State ought to be asked to co-operate with the Government to prevent the monopoly of the oil business and effectually to secure a reasonable price to the consumer. In my judgment this can be accomplished if the State of California should declare the consumption of oil a public use. The State should pass a law to this effect, and place the regulation of the price of crude oil in the hands of a discreet commission."

BUTTE, MONTANA

Davis-Daly Development. — Wild Bill Claim Sold. — East Butte Production.—Butte Reduction Co.—Tuolumne to Resume.—Rich Ore in Goldsmith.

There is an impression abroad that work has been discontinued in the Colorado shaft of the Davis-Daly company, but such is not the case. There is a force of men working every day on development, and, according to reports given out, some fair shipping ore has been opened; but following the policy announced by Mr. Heinze, no effort will be made to ship ore until the copper conditions show some signs of permanent improvement.——The Amalgamated Copper Co. has purchased the remaining half interest in the Wild Bill claim, having previously acquired the other half. This is a valuable property which is surrounded by such mines as the Speculator, Edith May, Ticon, Gray Rock, Corra, Rock Island, Chief Joseph, Ridge, and Miners' Union. Those who sold the half interest are John,

Elmira, Minnie K., Thomas C., and Frances Noyes, Alice Noyes Murray, and Mr. and Mrs. Arthur P. Heinze.——The East Butte company is said to be laying copper down in New York at 10½c. per pound, which includes all charges. The company is shipping to the smelter about 300 tons per day at present, and when conditions warrant it the output will be doubled. Driving on the new orebody discovered on the 800-ft. level shows every evidence of permanency. Two-thirds of the ore being hoisted now is first-class, running 8% copper; the second-class ore averages close to 3 per cent.

The concentrator of the Butte Reduction Works is to have some new equipment for the treatment of zinc ore. The only ore being concentrated regularly is that from Clark's Elm Orlu mine, and as this is not enough to supply the plant, it is hoped to secure for treatment some of the ore from the Butte & Superior mine.——Eastern capital has been secured for the Caroline Gold Mining Co. and a double-compartment shaft is to be sunk on its property in Grizzly Park, about five miles south of Helena.

The Tuolumne, being now free from all litigation, is to be put in condition to operate on a large scale. A steel head-frame, a first-motion hoist, and steel ore-bins constitute the principal part of the new equipment decided upon at a recent meeting of the directors. As the Tuolumne is without railway connection, and as the company is under an outlay of 50c. per ton for hauling ore to the railway, it was decided to construct a spur from the main line to the mine. The shaft now has a depth of 1400 ft. and it was decided to sink to 2000 ft. For this work a hoist is to be installed at the 1200-ft. station, which has been enlarged. The head-frame and hoist are expected to be in place within five months, and in the meantime the company will continue shipping about 6000 tons per month. When the Anaconda company purchased the Butte Reduction Works from W. A. Clark, the existing contract for handling the Tuolumne ore was transferred to the Washoe smelter by the Clark interests. This contract expires next February, and the Tuolumne company will endeavor to make the best terms it can with either the East Butte company or the Washoe company.

The Pilot Butte Mining Co. has paid all the indebtedness against the property, which gives it a clear title thereto. Arrangements have been partly made for resuming work. Among those interested as directors are T. F. Murray of St. Paul, W. P. Jahn of Milwaukee, J. A. Percival of Minneapolis, Edward Hickey and J. W. Pratt of Butte. The Pilot Butte has been opened by a 530-ft. shaft, and is considered in good territory.——A discovery of silver and gold ore in the Goldsmith mine at a depth of 100 ft. has caused some interest in mining circles. The property is being operated by miners whose lease expires in a short time. One car of ore netted $17,000, and since the find was made a few weeks ago the lessees have received over $200,000 from the sale of ore. The ore runs as high as 600 oz. in silver and $200 in gold per ton, and the lessees are mining and shipping as much ore as possible before the expiration of the lease. The Goldsmith is owned by C. W. Ellingwood, who worked the property for a number of years, and after realizing over half a million dollars, leased it. Now he proposes to work the property again himself just as soon as the lease expires.

PANAMA

The Journey Homeward of the Mining Engineers.—Compressed-Air Plant at Butte.—Proposed Mining Legislation.

The feature of Thursday, November 10, when a 7-hour stop was made at Kingston, Jamaica, was a luncheon given at the Myrtle Bank hotel by D. W. Brunton, to the 125 members of the party. It was an impromptu but a most enjoyable affair. At 5:30 p. m. the last of the cruise, the sail to New York, was begun. At the session of the Institute held Friday afternoon Charles W. Goodale, of Butte, Montana, presented a description of the new compressed-air hoisting plant at Butte. Electric power brought from the Missouri river plant, 130 miles distant, is to be used to compress the air to 90 pounds. The plant is to supply air for hoisting to 30 mines within a radius of three-fourths of a mile. Provision is made for storage capacity that will keep the hoists at work for 20 minutes after all power is shut off by accident or otherwise. The plant is being constructed by the Nordberg Engineering Co. for the Anaconda Copper Mining Co. The paper brought out a considerable amount of interesting discussion, as this is a decided innovation in hoisting installation. William L. Saunders, in reply to a question by Mr. Jennings, explained the difference between this plant and that in Paris which had failed. The difference lay in the fact that the Paris plant was installed for furnishing compressed air for all sorts of power purposes to a large number of small plants distributed over a wide territory, and that it could not compete with electricity which came to be used extensively about that time. The Butte plant, on the other hand, is to distribute large quantities of air to a few plants in a limited area, and the conditions are entirely different. William Kent gave a graphic illustration of the Butte scheme in a blackboard sketch. Other speakers were D. B. Rushmore, S. W. Warriner, Hugo Weinberger, William Keily, E. L. Watson, W. J. Richards, and D. W. Brunton. Mr. Brunton called attention to the fact that Aspen, Colorado, was the cradle of electrical hoists in the United States and that he had helped to rock the cradle. The session closed with the presentation by D. M. Riordan of a prepared statement embodying the sentiments that had been expressed at the session devoted to the discussion of the Canal.——On Saturday afternoon, after a brief paper by W. S. Ayres on losses in the preparation of coal, the report of the committee appointed by the American Mining Congress on revision of mining laws was taken up for discussion. First, Mr. Brunton read the report of the delegates of the Institute to the Congress, and then the report of the mining law committee, which has been distributed in pamphlet form, was briefly explained by Samuel A. Taylor of Pittsburg. The discussion that followed was exceedingly lively. Charles Kirchhoff called attention to one of the provisions that mine inspectors should have no connection with, or interest in, a mining company. He suggested an amendment to the effect that they should also have no affiliation with a labor organization. Eugene McAuliffe, of Chicago, aroused considerable amusement but at the same time showed the serious condition of affairs in the Mississippi Valley coal States, by depicting the conditions obtaining there as a result of legislation and the domination of the labor unions. He said it had got to such a state that the meetings of the operators had become 'talkfests' that would make excellent opera-bouffes, for during this last summer, after a strike of 5 months and 19 days, they went out and paid the labor leaders to sign the contracts. Mr. Brunton told about the mining laws in Australia and New Zealand as he had had opportunity to observe their operation, and Gardner F. Williams from his experience in South Africa told how much more efficient was the enforcement of and the respect for the law in the British colonies than in the United States. Inspectors are uninfluenced by politics and do their duty. Hennen Jennings found entire sympathy in his protest against the provision of secrecy. He said that in the Rand the publication of all facts in regard to mining operations had done no harm, but had been distinctly beneficial. S. D. Warriner paid a high tribute to the work of the Anthracite Strike Commission and that of the board of conciliation created by its award. He said that since the awards of the commission had been in effect there had been unprecedented peace and prosperity in the anthracite region. He is, however, looking with some feeling of apprehension to the termination in 1912 of the present contract, fearing that in a presidential year the miners may make an effort to disturb the present peaceful conditions. R. B. Watson told of the effects of too much law in Canada. The general feeling expressed was that while there was a great deal of good in the proposed reforms, the draft was fundamentally weak in spots, and would not bring the desired results. The failure to provide for proper disciplinary control is the weakest feature of the proposed law. It is

well known that more than half of the accidents are due to inability to enforce discipline, and yet the committee sidesteps the proposition with the ease and grace of a politician. On Sunday morning divine services were held in the ladies' saloon, Dr. Raymond preaching. In the afternoon Robert P. Porter, of the editorial staff of the London *Times*, and formerly superintendent of the Eleventh U. S. Census, gave an exceedingly interesting talk on South America, which continent he had been recently touring in the interests of the 'Thunderer'. Mr. Porter happened to meet the mining engineers in Panama, and as he was well and personally known to many of the party, he was invited to return to New York on the *Prinz August Wilhelm*. The final session was held on Monday afternoon, the principal feature of which was a paper by Joseph W. Richards, of Lehigh University, on the electrical manufacture of steel. Previous to the presentation of Mr. Richards' paper, Dr. Raymond read a statement which, with any amendments adopted, was proposed to be signed by the members and guests present. In it are expressed the opinions upon which all were in agreement, and as a whole it is a strong endorsement of the present Canal plan and of the manner in which it is being carried out. The time for arrival in New York was 10 o'clock Tuesday morning, November 15, but owing to head winds and the fact that the machinery was not working satisfactorily, it was 7 o'clock in the evening when the steamer reached her dock. As soon as the customs regulations had been complied with, the members of the party hastily departed for their homes or outgoing trains, and a most delightful cruise and one of the most interesting and illuminating meetings of the American Institute of Mining Engineers was ended.

LONDON

Affairs of Huelva Copper & Sulphur. — The Zeehan-Dundas. — Half Year at Mt. Lyell.—Jumpers and Treasury Mines.

A Spanish pyrite company that has been through rough times is the Huelva Copper & Sulphur which was formed in 1903. The control is in France, though the registered office is in London. The management and administration proved unsatisfactory and in 1909 a drastic reorganization was effected. W. J. Barnett proceeded to Spain and made a thorough examination, and Henry F. Collins was appointed manager in September of that year. When the new board enquired into the financial position they found that the capital subscribed had been applied for all sorts of doubtful purposes, none of them connected with the proper development of the mine. Not only so, but a ruinous contract had been made for the sale of pyrite, and that money had been received for it in advance of delivery. The progress of the company has therefore been impeded, and the policy has been to mine just sufficient ore to fill the unfortunate contract and to put all energies into the development of the orebodies. In order to reap adequate profit the consulting engineer and the manager are united in recommending smelting on the spot, but this policy has to be postponed, as there are no available funds. In the meantime efforts are being made to call in some of the money abstracted by the previous directors who have been forced to assume personal responsibility. When the company has straightened its finances and the engineers have developed the mines further, there will be an opportunity for the provision of further working capital. Mr. Collins' report, dated August 2, shows that at the Romero, Angelita, La Corta, and San Alberto mines there are large reserves of copper ore suitable for smelting and cementation, and much ore valuable for its sulphur content. During 1909, about 25,000 tons of 5% ore was shipped, and about 45,000 tons was sent to the cementation grounds.——The Mount Zeehan Tasmania Silver Lead Mines, after yielding profits for 20 years, became exhausted a year ago. Further prospecting and development have as yet yielded no results. Recently Thomas Vincent, the manager, heard of important discoveries at Dundas, 6 miles distant, and on his own responsibility secured an option. This property proved to be of great promise and the company completed the purchase. A subsidiary company, called the Zeehan-Dundas mines, was formed with a capital of £20,000, half of which has been provided by this company and the remainder by the Zeehan-Montana and other allied companies and by individual shareholders. The Zeehan-Dundas property is in the primeval forest and some of the galena veins 2 ft. wide stand out above the peat and soil. The outlook is most promising. The tailing heaps belonging to the Mount Zeehan have not yet been treated and experiments show that a slight modification of the existing plant will afford a ready means for their beneficiation.——The Mount Lyell Mining & Railway has published by cable the results for the half-year ended September 30. The amount of ore treated was 198,617 tons, of which 126,707 tons came from the Mount Lyell, and 71,910 tons from the North Mount Lyell. The average content was 2.41% copper, 1.78 oz. silver, and 0.58 dwt. gold. The produce was 4077 tons of blister copper, containing 4028 tons copper, 325,509 oz. silver, and 5672 oz. gold. The total ore treated was 9000 tons greater than in the previous half-year, and the output of blister copper was 87 tons less, the reason being that some of the ore from the North mine was of rather lower grade than usual. As regards the half-year ended March 31 it was stated that 1359 tons of copper remained unsold. It is now reported that this was subsequently sold at £59 per ton. Of the production during the last half-year, 3241 tons has been sold at an average price of £57 7s. 10d., leaving 787 tons unsold. After paying £5594 for taxes, and charging £10,147 to depreciation and £10,031 to exploration and removal of overburden, the net profit was £90,533. This figure is about £25,000 less than during the previous half-year, due chiefly to the decreased price of copper. The dividend absorbed £75,000, being at the rate of 1s. 3d. per £1 share. The cost of producing blister copper was 16s. 5d. per ton of ore, practically the same figure as before. The reserve on September 30 was 2,720,693 tons at the Mount Lyell, assaying 0.53% copper, 1.96 oz. silver, and 0.56 dwt. gold; and 927,683 tons at the North mine, averaging 6% copper, 1.33 oz. silver, and 0.1 dwt. gold. The addition to the reserves is 85,520 tons, a greater increase than during any previous period. At the North mine the orebody on the 850-ft. level is in places of greater size than was anticipated and developments on the 1050-ft. and 1100-ft. levels are giving good results. In addition to the copper ore, 3751 tons of sulphur ore from the Mount Lyell, and 4706 tons from the Chester mines were sent to the acid works. Prospecting continues at the Norfolk range properties, and though there is some encouragement for further work, nothing of real value has yet been found.——The Jumpers is one of the original outcrop mines in the central Rand, and, as its name implies, is a small portion of what would have been Geldenhuis ground if the surveyors of the latter company had worked accurately. The mine is now nearing exhaustion. It belongs to the Wernher-Beit-Eckstein group, and S. Richards is the manager. During the year ended July 31, 150,329 tons of ore was raised, and after the removal of 35% waste, 98,196 went to the mill. The average number of stamps in operation was 85 out of 100. The total production of gold by amalgamation and cyaniding was 43,953 oz. or 8.95 dwt. per ton of ore milled. At this mine sorting both below and at the surface is done closely and the policy of large output and low cost is not adopted. In addition to the mine ore, 24,014 tons was taken to the mill from the dump, and 40,382 tons of accumulated slime was treated by cyanide. The total expenses were £155,276, and the profit was £62,435. The dividends absorbed £40,000. With regard to the future of the property, Mr. Richards estimated the reserve on July 31 at 63,523 tons, but anticipates that as much again will be ultimately available from new ground and from old stopes; 6000 tons of old dump is profitable, as also is 42,000 tons of accumulated slime. As already reported, negotiations are in hand for the joint working of the Jumpers and the Treasury mine, whereby the former will conduct the remaining operations and take two-thirds of the profit.

General Mining News

ALASKA

(Special Correspondence.)—There is considerable excitement at Nome and throughout Seward Peninsula over the new finds on Squirrel river, a tributary of the Kowak or Kobuk river, which empties into Hotham inlet on the east side of Kotzebue sound. Gold has been found along Cleary creek, a tributary of the Squirrel, for a distance of four miles, and sluicing operations during the latter part of this season have disclosed rich ground. From $100 to $300 per day per shovel has been mined. The gravel beds are shallow, being from five to eight feet deep, and the gold is coarse. I have recently seen two pokes of Cleary creek gold, worth about $15,000, which were brought to Nome by H. Greenberg of the Bessie claim. This gold was in nuggets ranging from five cents to $100, and I was informed that this represents the run of gold as taken from the sluices. There are deep deposits of gravel on the benches of the streams, and prospecting for ancient channels is now being conducted by those who are wintering in the camp. About 400 miners are in the vicinity of Cleary, and others are now on the way there. Gold has been found on four creeks, but Cleary is the only one upon which sluicing has been done. This stream is about twenty miles long, and all of its gravel is believed to be gold bearing. Baldwin creek is of about the same length as Cleary, and good prospects are said to have been found on this stream also. Nome miners who have visited the district predict a great future for it, some going so far as to say it will be a better camp than Nome ever was. About $60,000 worth of gold was mined there in a short time just before the freeze-up this fall.

Nome, November 1.

(Special Correspondence.)—The steamship *Peteriana* took a 2000-ton cargo of ore from the Mt. Andrew mine, on Prince of Wales Island, last week to the Tyee smelter at Ladysmith, B. C. This ore samples high in iron and carries some copper.——Sheppard & McKenzie have started development work on their property on Dall bay.——The Pacific Metals Co. has a force of men on the Dean property cross-cutting toward an ore-shoot at the 90-ft. level. W. L. Poison is now superintending the work, succeeding John Hampson, who has gone to England.

Ketchikan, December 1.

The gold shipped by Alaska operators to the U. S. Assay Office at Seattle for the month of November 1910 amounted to $1,558,234.57, as against $722,780.67 for November 1909. It is noted that the 1910 operating season was considerably longer than previous seasons.——The mail and passenger route between the sea coast and Fairbanks is now from Cordova instead of Valdez, as formerly. The change was brought about as the result of building the railroad from Cordova a distance of nearly 100 miles up the Copper river. ——A custom stamp-mill has been built and put in operation at Chena, at a cost of $25,000. It is to operate on gold-bearing quartz mined in the hills near Chena and Fairbanks.

ARIZONA

COCHISE COUNTY

The Centurion mine, situated half a mile from Dragoon station, has been opened to a depth of 425 ft. on a vein said to be at the contact of limestone and porphyry. The vein strikes north and south, and has a dip of about 57°, the ore consisting of azurite, malachite, and chalcocite, with some native copper. It is claimed there are 5000 tons of ore on the dump, assaying higher than 3% copper. Contracts have been made with the owners of the smelter at Benson for treating this ore, as it is said that plant is to be operated again.——At the Copper Queen smelting plant, at Douglas, work has commenced on two reverberatory furnaces, and six McDougall roasters. Extensive additions are being made to the flue-dust chambers. Construction improvements are also to be made this year at the smelting plant of the Calumet & Arizona Copper Company.

GRAHAM COUNTY

The Arizona Copper Co. is taking steps to increase the capacity of one of its concentrating plants at Clifton from 800 to 1500 tons daily. A new working shaft is to be sunk close to the mill to be enlarged. For this work considerable new equipment will be required.——The Twin Peaks M. Co. is to build a power plant at York station, and transmit power to its mine and mill.

YAVAPAI COUNTY

The United Verde Extension, near Jerome, is being developed from an 800-ft. shaft. A level driven from the 800-ft. station has opened an extensive body of copper sulphide and farther on a deposit of carbonate ore. A winze was sunk 200 ft. from the 800-ft. level, and driving from the bottom of the winze is progressing to cut the same orebodies that were opened upon the 800-ft. level.——The Lincoln mine, situated in the Bradshaw mountains, has been sold by C. J. George and associates, to Miller and associates, who formerly operated at Goldfield, Nev. The mine has been considerably developed, and is equipped with a mill. The purchasers have a force of men at work in the mill and mine preparing to resume regular work. It is claimed the purchase price was $100,000.——Churn-drills are to be brought into use in exploring the holdings of the Cumberland M. Co., situated in Turkey Creek district. People of Des Moines, Iowa, are in control of the company.

YUMA COUNTY

A rich vein of ore has been discovered in Old Woman mountains, 16 miles from Milligan station, east of Parker, and locations covering it have been made by A. B. Day and Scott Price, whose assays of the ore show that it runs high in silver, with considerable copper, lead, and gold. Many other prospectors have gone into the new district to make locations.

CALIFORNIA

BUTTE COUNTY

Cohn & Goodday, purchasers of the Mineral Slide placer mine, near Magalia, have adopted the Moody amalgamating table to use in place of the sluice-boxes. The table was devised by S. P. Moody, and it is claimed that 95% of the gold is recovered by it.

CALAVERAS COUNTY

(Special Correspondence.)—The Standard Amalgamated Exploration Co. is building a chlorination plant at its Economic mine, of which Oliver Reece has charge. V. M. Weil, general manager for the company, recently arrived at the property from Boston.

San Andreas, December 3.

INYO COUNTY

The Southern Belle mine near Bishop is to be operated again, this time under bond to R. R. Hill of New York, and with A. E. Vandercook in charge of the work.——The Mollie Gibson, situated in the White Mountains, is being developed by Denver people. Some rich gold ore has been found.

(Special Correspondence.)—A. R. Short and associates of San Jose, who recently leased the Cerro Gordo mines from the Four Metals Co., are working a force of 15 men and expect to commence ore shipments within 30 days. An excellent orebody has been opened on the eleventh level.—— The Mortimer M. Co. of Philadelphia, having a property 12 miles from Lone Pine, has developed some good ore, and may build a 20-stamp mill and equip it with amalgamating and concentrating machinery next spring. A. B. Bell is general manager.——The Buckeye M. Co. has suspended operations pending an overhauling and alteration of the plant.——Eastern capitalists have bonded the Chrysopolis group and are installing a 10-stamp mill. Good bodies of ore are said to have been developed.——The Minnietta has resumed shipments of silver-lead ore. John Gunn is directing the work.——Operations have been resumed at the Keynote, 12 miles east of Lone Pine, on which developments will be carried on at greater depth.——Development work is in progress at the Ville Real, seven miles from Darwin,

where rich silver-lead ore was recently found by D. F. Shiveley. Samples of the ore are said to assay 60% lead, and 40 oz. silver per ton. The property is thought to be on the line between the Cerro Gordo and Darwin mines. The vein is over 8 ft. wide at the point of intersection.——The entire Lone Pine district has shown renewed activity with the completion of the new branch of the Southern Pacific.

Bishop, December 1.

KERN COUNTY

The Windy mine, close to Randsburg, has been opened to a depth of 400 ft. and has considerable ore on the dump. Some of the richer ore has been milled at a custom plant. It is the property of John Singleton.——The Butte is yielding ore that mills $50 per ton.——Some good milling ore is also being taken from the Zachray lease on the King Solomon vein, a small shipment of which yielded $100 per ton at a local mill.

NEVADA COUNTY

The Grover-Murphy quartz mine, west of Nevada City, has been sold to the Honoluiu company which has been operating it for the last two years. The final payment recently was made by S. D. Gynlais Walters, who came from Honolulu for that purpose. The former owners were Newton F. Grover, Mrs. K. M. Williamson, Frank Van Worter, and W. F. Murphy. Since the purchasers have had possession of the mine they have spent $30,000 in development work under direction of Harry B. Gray. The property is equipped with a hoist, pumps, and an air-compressor. An incline shaft was sunk to a depth of 350 ft., and from it there is 400 ft. of driving on the vein. The purchase price was $20,000.——The Morning Star mine, on Badger hill, has been bonded by John Curnow and others to a company of Berkeley men. The property is to be reopened, with Andrew Deon in charge. It has a 190-ft. shaft, which is to be unwatered and sunk deeper. Included in the equipment is a 10-stamp mill.

SHASTA COUNTY

The Copper Mountain Con. M. Co., controlled by Fiilius, King, and Grotefend, is now able to obtain patent from the Government for what is known as its Sugar Loaf group of 17 lode claims lying between the holdings of the Mountain Copper Co. and those of the Balaklala, in the vicinity of Keswick. This company's application for patent was held up for two years as the result of a protest made by the Central Pacific Railway Co., in which it claimed the land. In October, this year, the protest was withdrawn, and it is expected that patent will be issued in the next few months.——The Mammoth Copper Co., whose smelting plant is at Kennett, is to blow in its third copper furnace this week. There are two other furnaces not in use. It is understood that the operating capacity of the plant is restricted by the limited capacity of the bag-house which takes the fume and smoke from the furnaces.

SIERRA COUNTY

E. A. Bauder has given a lease and bond on the Middle Yuba gold quartz mine to Walter Bernard of Jamestown. The property is situated on Middle Yuba slope of Lafayette ridge, in the vicinity of Alleghany. It is developed by a 175-ft. adit on the vein, by which considerable depth is gained. Bauder has taken a contract to do further development.

SISKIYOU COUNTY

The Greenhorn group, close to Yreka, has been bonded by Claude E. Gillis to a company of Bakersfield men, the price named being $50,000. This is a placer property which is to be tested by the prospective purchasers to ascertain its value as dredging ground. It is said they are operating dredges elsewhere.——The Highland mine, owned by J. M. Tetherow, R. S. Taylor, G. A. Tebbe, J. M. O'Neil, and the estate of George D. Butler, is reported sold to a Hague syndicate, represented by F. Hulshof Pol.

TUOLUMNE COUNTY

(Special Correspondence.)—The company operating the mine in the past known as the Ida Klein has changed the name to the 'Berkeley.' Grading for the mill is in progress, and preparations are being made to install a hoist and erect a head-frame. W. J. Wyeth is superintendent.——Development work is again being done at the Martin gravel mine, situated near the property of the Gold Ship Mining Co., and prospects are said to be good.——The crew at the Jumper has been increased to about 50 men.——The mill at the Dutch is again in operation.——A body of rich sulphide ore has been uncovered at the property of C. C. June, at Moccasin creek. The vein is 4 ft. wide.——An inspection of the property of the Springfield Tunnel & Development Co. was made last week by William Hannon, of Tacoma, Washington, said to be one of the principal stockholders.——A shaft is to be sunk 200 ft. on a promising vein at the Sargent ranch, in the Groveland district, by Walter King. Work is to be commenced at once.——George Caplinger, of Hanford, and associates will commence the development of a gravel property near Chinese in which they are interested.

Tuolumne, November 28.

COLORADO

CLEAR CREEK COUNTY

A controlling interest in the Santiago mine in East Argentine has been purchased from William Rogers by the Santiago-Montezuma Development Co., the larger shareholders in which are also heavily interested in the North American Smelter & Mines Co., owners and operators of the smelting plant at Golden, the furnaces of which have been in blast since July 1. The smelting company has a contract for the ore to be produced at the Santiago mine for the next five years. It is claimed Santiago ore has an average value of about $24 per ton; that the shipments of 800 tons per month sample about 5% copper, 1 oz. gold, and 20 oz. silver per ton. The shaft is to be sunk 500 ft. below the present deepest workings, and a connection is to be made between the Waldorf adit and the bottom of the shaft when sunk to the depth indicated. This connection will require 900 ft. of driving.

FREMONT COUNTY

The United States Reduction & Refining Co. is building a plant at Florence to treat by cyanidation the tailing at the old Union mill, which is to be pulverized to a finer mesh by tube-mills. It is estimated that there are 100,000 tons of the stuff, of an average value of $1.10 per ton. It was formerly roasted at the Union mill.

GILPIN COUNTY

(Special Correspondence.)—The Newfoundland shaft has been repaired to the 200-ft. level. A new ore-shoot is reported on the lower level.——Shipments of ore are going out from the Baker mine on Quartz hill. The vein is 4 ft. wide. The concentrate samples 1.42. oz. gold per ton.——The East Notaway mine is becoming one of the largest shippers of the district. T. Martin, the superintendent, reports finding a new ore-shoot on the 655-ft. level. ——A shipment of ore was made last week from the Gulch mine in Lake district. The ore was taken from the 440-ft. level and milled 2.26 oz. gold per ton.——The new plant of machinery at the Pittsburg mine will be started up in a few days.

Central City, November 29.

Oliver & Jones, operating the Mitchell mine on Quartz hill, in November shipped 97 tons of ore to the Iron City concentrator, which made a saving of 84%, the gross value being over $20 per ton. They are doing considerable development work.——Pintarella & Co., lessees of the Champion mine, shipped 10 tons of ore that sampled $25 per ton. They have opened two veins of ore of smelting grade, and their shipments will now be larger.——Shipments from the East Missouri mine, on Quartz hill, amount to 20 tons per month, the ore running over $20 per ton. Pat Reid and associates are the operators.——The National, on Quartz hill, being developed by a company of local miners, has a 583-ft. shaft, with no levels driven below the 446-ft. station. The vein opened has a width of 4 to 7 ft., and is believed to be identical with the Mammoth vein, which was mined to a depth of 1400 feet.

LAKE COUNTY

J. B. Moore and George Higgins, lessees of part of the Ella Beeler in Iowa gulch, after prospecting and developing several months, have found an 18-in. vein of lead, gold, and silver ore assaying $85 per ton. This was found by driving from an old 850-ft. adit. It is thought this streak of ore may lead to the main ore-shoot.——Dwyer & Bittner, working the Gold Coin on Half Moon gulch, have driven a 180-ft. adit, cutting a narrow vein, the ore in which assays $60 to $100 per ton. The ore being mined by them is carried by pack-animals down to the wagon-road, as the mine is on a steep mountain-side. A small shipment to the smelter has been made——Burton, Thelin, and Kirk White are shipping 40 tons daily of zinc carbonate ore from the Hayden shaft, on Fryer hill. It is said to run 40% zinc. An electric hoist is being put in at this shaft.——The Seneca, on Strayhorse gulch, is being operated by Burton & Thelin, who are installing at the Seneca shaft an electric hoist. They expect to find zinc carbonate ore.

OURAY COUNTY

The American-Nettie mill, built in 1901, by the American Gold M. Co., and which was idle for a long period, is now in the hands of the Wanakah M. Co. This company has rebuilt and modernized the mill and started it in operation on ore from the Bright Diamond mines. The mill is now equipped with a 9 by 15-in. Blake crusher, picking table, 20 stamps, and 8 Wilfley tables, and has the capacity of 70 tons per day. The mine is said to have considerable ore accessible, the metals being gold and silver. G. H. Barnhart is the company's manager.——A company of Boston men has commenced the work of erecting a smelting plant at Red mountain, the equipment for which is to be supplied by the Traylor Engineering Co. The persons identified with the smelting enterprise have acquired the Saratoga, Alvarado, Mono, and Baltic mines in the Red Mountain district.——The Carey Brothers have a lease on the American-Nettie and O. & N. mines at Ouray, from which ore is being taken and milled at a small plant recently erected. F. O. Seaberg, long identified with these properties, is manager. ——Lessees on the Khedive are reported to have opened a large body of valuable ore.——The Atlas mine in Sneffels district has not only been developed through the San Pedro adit, but through other openings. It has big bodies of ore and its mill is in successful operation.——The Revenue, up toward Mt. Sneffels from the Camp Bird, has a force of 240 men, the greater number of whom are on development work. The mill is being repaired and changed in some particulars.

SUMMIT COUNTY

The Standard mine, on Gibson hill, which is being operated by M. A. Wright and others, shipped to the smelters a car of ore that sampled $90 per ton in silver, lead, and gold. Other shipments are to follow. ——The Pfister-Smith lease on the Bulwer lode, Nigger hill, near Breckenridge, is now productive. An 18-in. vein of galena and lead-carbonate was recently opened as the result of driving from the bottom of a 60-ft. shaft.——Two carloads of sacked concentrate was shipped in November from the Arctic mine, on North Star mountain. E. P. Jones has charge of the mine and mill. The ore assays well in gold.——In operating the Reliance gold dredge on French gulch the buckets cut into the bedrock and scraped up some high-grade galena from the bedrock cropping of a vein of that kind of ore. ——The clean-up of the Reilling dredge, made the last week in November, amounted to over $8000; it was anticipated that the following weekly clean-up would exceed this. H. J. Reilling is directing these operations.

TELLER COUNTY

The Golden Cycle M. Co., operating near Goldfield, in Cripple Creek district, declared a dividend of one cent per share November 1, and another of two cents per share payable December 1. It is reported that this company is considering the plan of building an aerial tramway from Cripple Creek to its mill at Colorado City.——It is reported that a custom milling plant, in which the Portland process is to be adopted, is to be built in Cripple Creek district by an independent company.——The Portland leaching plant is to be increased in capacity. At present 1000 tons daily is being crushed.

IDAHO

BOISE COUNTY

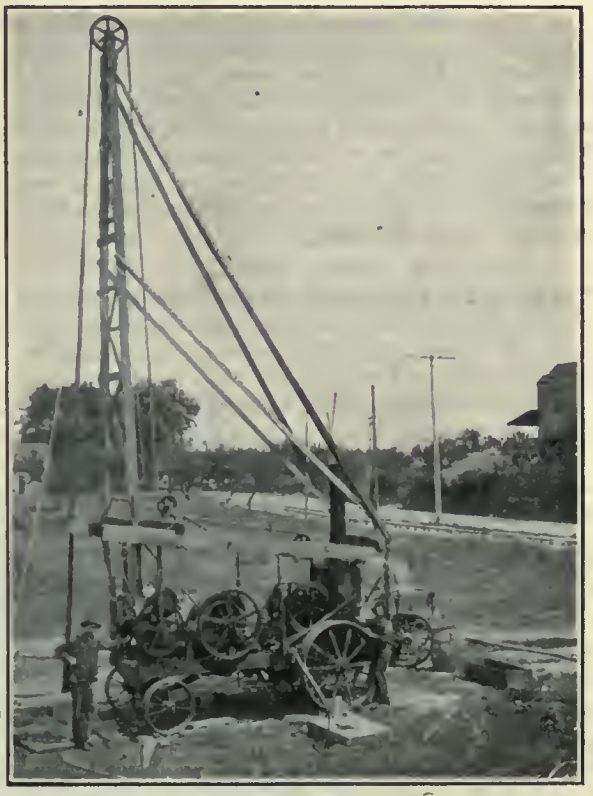
(Special Correspondence.)—The Centerville Mine & Milling Co., which last September lost by fire its plant for extracting monazite from the sand and placer tailing on Grimes creek, intends to rebuild the plant on a larger scale, but not until after it has completed the building of an electric-power plant on the Payette river at a site 16 miles from the mining property at Centerville. It is estimated that the latter will not be accomplished before 1912. The company has completed a system of 60 miles of ditches to carry water for hydraulic placer mining which is to be started on Grimes creek next spring.

Centerville, December 3.

MISSOURI

JASPER COUNTY

(Special Correspondence.)—Preparations are being made throughout the district to reopen old properties which have been idle for some time. In the Webb City field the old



Prospecting at Joplin With a Keystone Drill.

Electric mine on the Guinn land is to resume operations. It is a sheet-ground property operating on rather thin dirt at a depth of 200 ft. The new company will enter the ground through the old incline shaft.——The old Holdout mine in the north Webb City sheet-field is to be operated again under the management of the American-Canadian Co. The dirt is taken from the 175-ft. level. Zincblende and no lead is found.——The Providence company has taken over the Siegfried mine on the Newell-Morris land south of Webb City and will begin operating. During the idleness the drifts filled with water and pumps have been installed to unwater them. A number of drill-holes have been put down and the deposit blocked out.——Joplin operators have taken over the Porter tract west of the Missouri Pacific station in Carthage and have installed pumps to drain the property. Ore is rich here, lead being found at a depth of only 70 ft.——The operators of the Prairie Chicken, southwest of Joplin, are driving south from the new shaft and have connected with the old drifts. Ore is being taken from the 200-ft. level, where it is mainly zinc-

blende, with a small percentage of galena. The old tailing from this mine is also being worked by a leasing company. ——A 100-ton tailing mill is being built on the Lone Elm land of the Granby company. This mill will re-work the tailing from the 430-acre tract. It will be the first to operate in this part of the field for many years. The tailing is thought to contain a good percentage of metal. There are also numerous crush piles which were imperfectly treated by hand-jigs, and it is believed they will yield some ore.——A mill of 100 tons capacity is being built on the Saddler tract, south of Duenweg, to handle the calamine which is being found there in abundance. This ore is being taken from the 123-ft. level, and formerly was treated on hand-jigs. An ore face 40 ft. wide has been uncovered in one drift. Before building the mill the ground was thoroughly tested. In addition to calamine, there is some free lead ore in large chunks, easily prepared for the smelter. ——There is some activity in the Carl Junction camp. The Homestake mine has a new mill to be started at once. Before the work was planned the tract was most thoroughly prospected and the mineral extent determined.

Joplin, November 28.

NEVADA

CHURCHILL COUNTY

The work of building the mill at the Nevada Hills mine, at Fairview, is progressing rapidly under direction of J. B. Fleming, mechanical engineer. The plant is to have the capacity of 100 tons daily, and is being equipped for processes similar to those adopted in the mill of the Goldfield Consolidated. A steel head-frame is being erected at the principal shaft. W. H. Weber is manager for the Nevada Hills Con. M. Co., the controlling stock in which is owned by George Wingfield.

EUREKA COUNTY

The Eureka & Palisade railroad, and property connected with it, were purchased at foreclosure sale last week by George W. Heintz, general manager for the United States Smelting, Refining & Mining Co. The road has a length of 86 miles, extending from Palisade to Eureka, and has not been in operation since last March when serious damage to the property by high water occurred. The United States company owns the old Richmond-Eureka mines at Eureka, the ores of which consist of lead-carbonate, associated with iron, with sulphide ore in the lowest workings. It is assumed that this company may rebuild the railroad to make this lead-iron ore available for its smelters.

LINCOLN COUNTY

Reports published at Salt Lake are to the effect that the Pioche mining properties of the Nevada Utah, Consolidated Pioche, and Prince Consolidated are likely to be merged under one organization. It is understood that a definite basis of consolidation has been agreed on, and that the proposition is ready to be submitted to the stockholders of the three companies concerned. Among those who attended a meeting to arrange the terms of the proposed merger were Ernest R. Woolley, Ernest L. and Anthony H. Godbe, and Jas. L. Hackett. The successful termination of these negotiations probably will be followed by activity on a large scale in Pioche district.

NYE COUNTY

(Special Correspondence.)—Companies owning property surrounding the Tonopah-Belmont, encouraged by the development in the latter which has placed it in the first ranks of Tonopah producers, have resumed development work after several years of idleness.——The Mizpah Extension, adjoining the Belmont on the north, after sinking 1000 ft., is now driving north from the 1000-ft. station. The shaft is in rhyolite, but the drift is expected soon to enter the andesite, or lode-hearing formation, as the Belmont shaft passed through the rhyolite at about 850 ft. The driving progresses slowly, as it is being carried on by hand drilling. A compressor for air-drills is soon to be installed, however.——The Rescue-Eula, south of the Belmont, has repaired its shaft and started development. The lower levels are in the lode-bearing andesite, and a drift on the 600-ft. level connects with the Belmont workings. ——The North Star shaft, directly north of the Belmont's Desert Queen shaft, is being put in order after an idleness of three years. This property has several proved veins of fair promise.——The last property to resume work is the Belmont Extension, owned in part by George Wingfield. It lies southeast of the Belmont and adjoins the Rescue. The surface plant, head-frame, and top sets of the shaft were destroyed by fire some time ago, and these are being replaced so that sinking can he resumed at the present depth of 425 ft.——The Jim Butler Co. has commenced repairing the surface plant at the Stone Cabin shaft in which a skip is to replace the crosshead and bucket. Driving will be started southeasterly on the 600-ft. level, to be continued beyond the Stone Cabin fault into virgin ground. ——The Montana-Tonopah has declared a 6-cent dividend, payable December 20; and Tonopah-Belmont has declared a 15-cent dividend, payable January 15. In October the net earnings of the Tonopah were $165,000, those of the Belmont being $102,000. The Tonopah has discontinued work on the Sand Grass shaft, except that two diamond-drill holes are being put down on the claim to find the depth of the later andesite capping, and to prospect the lode-hearing earlier andesite.

Tonopah, December 1.

WHITE PINE COUNTY

The shaft of the Giroux Con. Mines Co., at Kimberly, is being sunk from 1300 ft., its present depth, to 1400 ft. Cross-cuts from this shaft east to the Alpha orebody have been driven from the 1000 and 1200-ft. stations, and a similar cross-cut is to be driven from the 1400-ft. station as soon as the shaft shall have reached that depth. The length of these cross-cuts is about 750 ft. By this system of opening it is planned to explore thoroughly and develop the orebodies. This company has appealed to the Interstate Commerce Commission to have established a through freight rate from Chicago and Missouri River points to stations on the Nevada Northern. The company probably will not proceed with the building of a smelting plant at Kimberly until this rate question is settled. It is the local rate over the latter road that is complained of as being excessive.——The Steptoe Valley S. & M. Co., a subsidiary of the Nevada Consolidated, which operates the big concentrator and smelter at McGill, is now concentrating between 8000 and 9000 tons of ore daily from Copper Flat. Three basic-lined converters are being installed in the converter building at a cost of $120,000.

NEW MEXICO

GRANT COUNTY

The Chino Copper Co. acquired its present holdings of 2800 acres in 1909. Included in this area is the old Santa Rita copper mine, operated a century ago by Spaniards. It is regarded as the oldest copper mine in the United States. Its location is close to Santa Rita, east of Silver City. The ore is disseminated through porphyry and quartzite, in which the company has developed extensively. Its ore reserves on November 1 were estimated at over 30,000,000 tons, which, according to sampling, assays 2.6% copper. To concentrate this ore the company is erecting a plant of 3000 tons daily capacity at Hurley, nine miles from the mine. The Santa Fé railroad branches extend to Silver City and Santa Rita from Deming.

OREGON

GRANT COUNTY

The Red Boy Mines Co., owning the Red Boy mine and mill, situated four miles from Granite, has increased its capital stock from $1,000,000 to $1,400,000, and authorized the issuance of bonds in the amount of $150,000 for the purpose of paying the indebtedness of the company, and creating a fund for further development. The lower workings are kept drained and the plan is to sink 300 to 500 ft. deeper and explore the orebodies from the lowest station.

JOSEPHINE COUNTY

Activity in placer mining is reported in the vicinity of

Kerby and Waldo, in Illinois valley. Hoisting equipment has been put in place at the Deep Gravel mine at Waldo; and in prospecting the Greenback gravel mine pay-ore has been found at a lower depth than heretofore. A boiler and other equipment have been hauled out to the latter property recently.——the Alameda Mining Co., whose mine and smelting plant at Galice are on the National Forest, had to give a bond of $10,000 to cover any damage to the standing timber in that vicinity that may result from smelter fume.. This bond being given, the District Forester granted a special permit whereby the smelting furnace may be operated.——The Blalock placer mine, situated near Placer, has been leased to John Willtrout and son, who have put in some new hydraulic pipe. They have commenced operating.——The Scandinavian-American Dredging Co. has been organized to dredge for gold the bars and banks of the Rogue river. P. H. Holdsworth, W. L. Hunter, Joseph Stumpf, W. Martin, and others of Seattle are the organizers. It is stated that a dredge has been purchased, and that it is being installed near Grants Pass.

UTAH

JUAB COUNTY

Ore shipments from the mines of the Tintic district, for the week ended December 3, were as follows: Centennial-Eureka, 53 cars; Chief Con., 5; Dragon, 15; Sioux Con., 8; Iron Blossom, 19; Colorado, 9; Opohongo, 1; Grand Central, 4; Uncle Sam, 5; May Day, 3; Gemini, 3; Iron King, 3; Yankee, 1; Gold Chain, 7; Scranton, 4; Ridge & Valley, 3; Eagle & Blue Bell, 1; Mammoth, 1; total, 125 cars. In addition to this, the May Day shipped one car of concentrate. The Tintic mines are mostly in limestone, which forms the Tintic range. A number of the mines have been opened to a depth of over 2000 ft., notably the Centennial-Eureka, Mammoth, and Grand Central. In the Centennial-Eureka shaft water-level was found at 2200 ft., and at this station electric pumps were set. This property belongs to the United States Smelting, Refining & Mining Co., while the Iron Blossom and Colorado belong to Jesse Knight; the Uncle Sam and May Day are owned by companies of which John Dern is general manager. The Gemini, one of the oldest mines in the district, is owned by the J. Q. Packard estate, and is in charge of McChrystal Brothers. The Chief Con., one of the newer properties, is in control of Michigan operators, for whom Walter Fitch is manager. The Chief shaft has reached a depth of about 1700 ft. The ores of the district carry lead, silver, copper, and gold. The Mammoth is especially noted for the large amount of gold in its ore. The towns of the district are Eureka, Mammoth, Robinson, Silver City, and Knightville, all of these except the last having connections with the San Pedro and Rio Grande railroads. Years ago there were four or five concentrating plants operating in the camp; now there is but one—that of the Uncle Sam. Moderate freight rates, and nearness to smelting centres, apparently have made concentration unnecessary.——The Colorado M. Co., controlled by Jesse Knight, mined and shipped 25,654 tons of ore during the last year, of a gross value of $823,217.49; net value, $579,209.91. The metals extracted from this tonnage of ore consisted of 4842.66 oz. gold, 919,841.09 oz. silver, 10,177,904 lb. lead. Dividends for the year were $400,000.

SALT LAKE COUNTY

The sixth reverberatory furnace, 300 tons daily capacity, is ready for use at the plant of the A. S. & R. Co. at Garfield; and another copper converter is almost ready to be operated.——Six sections of the Arthur mill of the Utah Copper Co. are being remodeled; the Nissen stamps are being replaced by Chilean mills. When finished the plant is expected to have the capacity of 7000 tons per 24 hours. This is what was formerly the Boston Con. mill. The capacity of the Utah Copper Co.'s Magna mill has been increased to nearly 13,000 tons daily.——A late report made to the stockholders of the Utah Con. M. Co. by that company's consulting engineer, gave an estimate of the ore in sight at 300,000 tons, averaging 2.32% copper, 0.05 oz. gold, 0.85 oz. silver. Recommendation is made that exploration and development be carried out in unexplored ground for the purpose of finding a higher grade of ore, if possible. The above estimate of available ore tonnage seems disappointing, as previous estimates had given a much higher figure. The mine of this company is locally known as the Highland Boy, and is situated on the upper end of Carr fork, in Bingham district. A considerable expenditure was made this year in the construction of an aerial tramway from the mine to the plant of the International Smelting & Refining Co., near Tooele.

SUMMIT COUNTY

A system of leasing has been adopted at the Daly West, Daly-Judge, and other mines of Park City district, which is said to be proving satisfactory to owners and lessees. The Daly-Judge M. Co. guarantees wages to lessees, but as a rule the latter make much more than the established wage. The plan is to let leases on small bodies of ore which cannot be worked by the company at much profit, but on which the lessee often can do well. When work on those small veins leads to a big body of ore, however, the company reserves the right to cancel the lease and work it on its own account.

WASHINGTON

FERRY COUNTY

The Republic Mines Corporation paid a dividend of $15,000 on November 28, which makes a total of $85,000 paid since June. In the meantime $200,000 has been paid on the purchase price of the mines, leaving a balance of $25,000, which probably will be paid before the end of the year. The money necessary to meet the above payments of $285,000 was part of the proceeds of ore sold since last January. The ore produced was taken from the Lone Pine, Surprise, and Pearl claims in Republic camp. The property was acquired from the Pearl Con. M. Co. of Spokane. J. L. Harper has been manager for the Republic Mines Corporation since the purchase was made.——The Beecher mine, situated near Orient, has been reopened. The 2-compartment shaft has been cleaned out, and mining commenced. This is a gold mine that formerly produced high-grade ore.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The Granby Con. Mining, Smelting & Power Co., operating at Phoenix and Grand Forks, has taken an option on the controlling interest in the stock of the Hidden Creek Copper Co. at $400,000, and has made a substantial payment. M. K. Rodgers of Seattle is the minority stockholder. A force of 25 to 30 men is employed at the mine and development is to be continued through the winter. The property is situated on Observatory Inlet, in the vicinity of Portland Canal.

Hidden Creek Copper Mine.

Prince Rupert, December 1.

(Special Correspondence.)—The intention is to continue shipments from the Aurora mine, at Moyie, all winter. The ore is being concentrated, the silver-lead product going to

Trail smelter; the zinc concentrate is to be shipped to the United States. The lower tunnel is to be driven to the main orebody.——The Estella group near Tracy, now under bond to John Sullivan, is said to have 3 to 12 ft. of ore in the adit that will assay 45% zinc. In the shaft 5 ft. of ore has been cut which assays 70% lead and 20 oz. silver. Over $125,000 has been spent on the property. Preparation is being made to ship ore.——The Van Roi mine has closed down pending the building of the new concentrator.——A find of rich silver ore has been made on the Sweetgrass, being operated under lease.——A find of good ore is reported from the Noble Five property. A 3-ft. vein has been opened on three levels.——It is with regret the mining men in the Kaslo district learn that the C. P. Ry. does not intend to take over the K. & S. Ry. from the Great Northern. The Government is negotiating with the G. N. Ry. in an effort to get the line reopened.——A discovery is reported on the Granite-Poorman near Nelson. The main vein on the Greenhorn claim has 350 ft. of backs. The ore has averaged $12 in a 2 to 3-ft. vein.——An adit is to be driven on the Eureka, Sheep creek, to open the seven veins on the property. A force of men is at work making a road to the proposed Mother Lode millsite, on which a 20-stamp mill is to be erected.——The shipments of ore and concentrate from the Slocan-Kootenay district for the week ended November 19, 1910, amounted to 1614 tons, of which 1024 tons was shipped from the Sullivan mine.

Nelson, November 25.

ONTARIO

(Special Correspondence.)—E. M. Flynn, general manager for the Porcupine Gold Mines Co., has gone to New York. He stated that reports from Porcupine greatly exaggerated the impassable condition of the trails; that the recent frosts have hardened the ground; and later frost and snow have made good sleighing. It is now possible to drive from Kelso, the point of departure from the T. & N. O. railway, to Crawford's Landing. The lakes and rivers are not yet frozen enough to allow teaming, but they are now teaming on the government road from Hill's to Porcupine. A floating bridge is being constructed across the Frederickhouse river, and it is only a question of a few days before it will be possible to drive through from Kelso to Porcupine.——On the two McKay veterans in southwest Tisdale, which were taken over by the Waldman Syndicate, two veins have been discovered. The mill of the Porcupine Gold Mines Co. will be in operation in about two weeks. The main working shaft is down 95 ft., and it is expected the main orebody will be reached and a station cut at 120 ft. within two weeks.——The Maiden MacDonald group of claims a mile south of Tisdale township, has been sold at a price said to be $250,000; the Josey group in Deloro has been sold for $150,000; the two Knapp claims in the northwest corner of Shaw for $36,000, and the three Foster-Ellis claims in Shaw township have been sold to the Temiskaming & Hudson Bay Co. for $35,000.——The reports of a discovery on the Penny veteran in Whitney township have been confirmed. A vein 600 ft. in length, with many exposures of free gold, has been uncovered. It is reported that important discoveries have been made on the Powell group in Deloro, south of Lot 7 in Tisdale, where a vein 32 ft. in width with rich gold ore has been uncovered.——A. H. Crampton, superintendent for the Porcupine Gold Ridge Mines Co., reported to the secretary of the Porcupine Mine Owners' Association today that the recently discovered quartz vein, in the southeast section of the property near Gillies lake, is from 8 to 12 ft. in width. The cropping was well mineralized, pannings from which showed free gold. Six samples carefully taken by Mr. Crampton were sent to Ricketts & Banks, whose analysis showed an average of 3.94 oz. or over $81 per ton in gold. Ricketts & Banks also reported that free gold was observed in the crushed portions of samples submitted. One very interesting development on this property is the fact that the schist, which is enclosed in the quartz veins, runs even higher in gold than the quartz itself.

Porcupine, December 1.

Technical Schools and Societies

The COLORADO SCHOOL OF MINES QUARTERLY for October, issued at Golden, deals ably with the 'Scope and Progress of the Mining Industry in Colorado.'

The INDIANA ACADEMY OF SCIENCE held its twenty-sixth annual meeting at Claypool hotel, Indianapolis, November 25. The program was of much interest.

The STATE GEOLOGICAL & NATURAL HISTORY SURVEY OF WISCONSIN has issued a relief map of the State, showing topography, geology, drainage, railroads, county lines, and cities.

E. R. BUCKLEY, geologist for the Federal Lead Co., lectured at the Missouri School of Mines, on November 7, on 'The Geology of the Disseminated Lead Deposits of Southeast Missouri.'

H. A. BUEHLER, director of the Bureau of Geology and Mines of the State of Missouri, lectured to the class in economic geology in the Missouri School of Mines on October 17 and 19 on the 'Origin of Zinc Deposits of Missouri.'

The UTAH SOCIETY OF ENGINEERS held a regular meeting on the evening of October 31, at which a paper on 'Manganese Steel' was read by F. E. Johnson. Members of the Society visited the plant of the International Smelting & Refining Company.

A number of former students of the MICHIGAN COLLEGE OF MINES met at a banquet in Chicago recently and formed there the Michigan College of Mines Club. The officers are E. C. Reeder, H. H. Hopkins, F. O. Williamson, and E. K. Stevenson.

The SCHOOL OF MINES OF THE UNIVERSITY OF WASHINGTON, at Seattle, has arranged a three-months course for mining men this winter, which includes instruction in stamp-milling, concentration of ores, assaying, drafting, sampling ores, geology, and surveying.

The UNIVERSITY OF IDAHO, at Moscow, mining department, has been equipped for assaying, ore dressing, and metallurgical tests. An eight-weeks course has been established for the benefit of those who cannot take the regular course in mining and metallurgy.

The SOCIETY OF ARIZONA ENGINEERS was organized at Phoenix last month, with the following engineers as officers: W. A. Farish, Phoenix, president; Geo. J. Roskruge, Tucson, vice-president; Mr. Gerold, Phoenix, secretary; P. P. Parker, Phoenix, treasurer.

The ZACATECAS MINING ASSOCIATION held a meeting at Zacatecas, Mexico, November 17, at which the question of having a geological survey of the district was discussed. The next meeting is to be held December 21. J. F. Barry, Mine La Fe, at Guadalupe, is secretary.

THE SCHOOL OF MINES OF THE PENNSYLVANIA STATE COLLEGE, co-operating with the mining branch of the State Y. M. C. A., has undertaken mining extension work among the coal-mining men of that State. This includes lectures on mining topics, and these are printed and distributed.

In the SCHOOL OF MINES OF PENNSYLVANIA STATE COLLEGE the following appointments have been made: H. D. Pallister, of the Case School of Applied Science, to be instructor in metallurgy; Victor Ziegler, of Iowa University and of Columbia University, to be instructor in geology and mineralogy.

UTAH COPPER CO. is producing copper at the rate of 85,000,000 lb. per year, and for 1910 the total output is expected to approximate 89,000,000 lb. Earnings, including $1,465,000 from Nevada Consolidated holdings, are estimated at $5,370,300.

NEVADA CONSOLIDATED production of copper in October is reported at 4,980,306 lb., a decrease from September of 3.3%. Production for the first ten months of the year amounted to 54,781,912 lb. copper.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

RE-LOCATION OF PLACER CLAIM

Where locators of a placer mine are at most in constructive possession only their location must be strictly legal and valid to be effectual against a person who seeks to relocate the ground.

Saxton *v.* Perry, (Colo.) 107 Pac. 281. Feb. '10.

TITLE TO MINING CLAIM IN PHILIPPINE ISLANDS

The possession and working of a mining claim in the Philippine Islands for the time required by the United States statute, in order to establish a right to a patent, need not have been under a claim of title.

Reavis *v.* Fianza, 30 Sup. Ct. Rep. 1. Nov. '09.

BOUNDARIES OF MINING CLAIM—FIELD NOTES AND MONUMENTS

The courses and distances in the field notes, and in the patent of a mining claim, are not conclusive of the true locations of the established monuments of the official survey. But a competent witness may testify that he saw and observed the posts and monuments and knew that they were not changed from their original position.

Grand Central Mining Co. *v.* Mammouth Mining Co., (Utah) 104 Pac. 573. Sept. '09.

VALIDITY OF ENTRY OF COAL LANDS

Under the United States statute permitting the entry of coal lands by a qualified person, in case of an individual, not exceeding 100 acres, and in case of a corporation not exceeding 320 acres, persons cannot lawfully associate themselves together for the purpose of entering tracts of 160 acres each in severalty, but to be held for the joint benefit of all in equal shares, and patents so issued were cancelled at the suit of the United States.

United States *v.* Portland Coal & Coke Co., 173 Fed. 566. Oct. '09.

ASSESSMENT WORK ON MINING CLAIM—CONSTRUCTION OF STATUTE

The statute of Washington providing that any mining district may make road building to mining claims within such claims applicable as assessment work upon mining claims, on certain conditions therein named, was held to apply only to organized mining districts. But independent of the statute, work done in connection with the claim but outside of it, if done for furthering the development thereof, is available as assessment work as if done within the boundaries of the claim itself; and the building of a road, where there is no organized mining district, to be used in the general development of the mining property, is doing assessment work within the meaning of the law.

Sexton *v.* Washington Mining & Milling Co. (Wash.) 104 Pac. 614. Oct. '09.

INJURY TO MINER—PROXIMATE CAUSE

A miner while riding out of the mine on the front bumpers of a cable car drawn up a slope, with his arm resting on the top edge of the car, came in contact with a stream of water escaping from a defective joint in a pipe used for pumping water from the mine, supported along the roof of the tunnel, and by reason thereof he was thrown around to one side and his arm was crushed against the roof of the tunnel, which was some 6 in. above the top of the car. In an action for the injury in order to render the mining company liable, it was decided that it was not necessary for him to show that the force of the water was sufficient to physically throw him around and bring his arm in contact with the timber; but that it was sufficient if it caused him to instinctively throw up his arm, and thereby receive the injury.

Tremont Coal & Coke Co. *v.* Johnson, 172 Fed. 785. Sept. '09.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

TESTING FOR METALLURGICAL PROCESSES. By James A. Barr. 216 pages, indexed, Ill. *Mining and Scientific Press*, San Francisco, 1910. Price $2 postpaid.

The engineer familiar with Western mining camps notes in them everywhere abandoned reduction works. The properties which they were built to serve may have been speedily mined out, but frequently there are those which have never turned a wheel. On further development the mine may have shown no more ore, or the ore has been found to be of too low a grade to work it at a profit. Again, failure may have resulted because the plant was unsuited to the proper extraction of the metals in the ore. To avoid this latter calamity it devolves upon the engineer who has to examine a mine to investigate the best methods of ore-treatment, and it is to aid him in making a selection that this book has been written. The author states his problem as follows: "Given an ore or a collection of ores, what are the metallurgical conditions to be attained to result in their most profitable treatment? The ultimate purpose of the investigation may be for a comparison of fine and wet methods, or for determining the commercial value of an ore." Concentration may be part of an ore-treatment scheme, and first an examination of the ore is made to determine the value and character of the associated minerals and the nature of the included grains. Then laboratory tests are made by jigging and by the concentration of the fine material on tables. If the ore requires it, it may be tested to determine its behavior with magnetic separation, electrostatic separation, or by ore flotation. If the ore contain gold or silver, then it should be determined to see whether it is amenable to treatment by the cyanide process, by chlorination, or by smelting. For the tests a correct sample is of the first importance. Then a preliminary investigation is made of the physical and chemical states in which the gold and silver exist, the fineness of grinding, the presence of heavy minerals suitable for concentration, the solubility of the gold and silver in the cyanide solution, the consumption of chemicals, and the precipitation of the dissolved metals. If the question is as to the relative advantage of cyaniding or smelting, then we must consider the final costs per ton as well as the comparative extractions by either method. In a separate chapter are given schedules of charges and penalties for smelting, so that the engineer may compute the relative advantages of the methods proposed. Thus he is put in possession of all the data from which to determine the most profitable method of treatment.

The book does not altogether confine itself to these matters. It treats also of the instruments and methods of determining the efficiency and performance of furnaces. In blast-furnace operations it takes up a discussion of the best composition of slags and details the methods of estimating charges. Finally, the author has collected in a separate chapter cost data of operating and of plant equipment, so necessary for an engineer who has to examine and report on a mining property. The most evident criticism that could be offered upon the book itself would be that the original drawings of the author should have been re-drawn before presentation. The low price of the book ($2) may be given as an excuse for omitting this. L. S. A.

PRACTICAL SHAFT SINKING. By Francis Donaldson. Pp. 143. Ill., index. McGraw-Hill Book Co., New York, 1910. Price, $2.

This, the latest addition to the literature on practical mining, will be welcomed by those who contemplate shaft sinking, or who are engaged in such work; particularly those who have unusual difficulties to overcome, where extraordinary methods must be employed, such as caissons, sheet-piling, pneumatic processes, freezing, and the like. The book also gives some valuable cost data and suggestions as to contracts in shaft sinking.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. FURNESS is at San Francisco.

J. W. ABBOTT has been at Los Angeles.

J. P. HUTCHINS was at Chicago recently.

R. A. F. PENROSE, JR., was in San Francisco recently.

LIONELL LINDSAY has returned to San Francisco from Mexico.

W. A. WILSON, of Salt Lake, recently visited Pioche, Nevada.

EDMUND JUESSEN has returned to San Francisco from Nevada.

J. B. TYRRELL has opened a branch office at Porcupine, Ontario.

V. M. WEIL is at the Economic mine, Calaveras county, California.

W. A. HARVEY is in charge at the Imperial mine, near Sumpter, Oregon.

J. D. HUBBARD has returned to Korea, leaving San Francisco December 6.

F. J. SIEBERT, manager at the Buckhorn mine in Nevada, is in San Francisco.

ERROL MACBOYLE has returned to San Francisco from the Philippine Islands.

NORMAN C. STINES will hereafter make headquarters at St. Petersburg, Russia.

A. C. BOYLE is professor of mining engineering at the University of Wyoming.

S. H. BRADY, manager for the West End Mining Co. of Tonopah is in San Francisco.

E. S. PETTIS was recently at Grass Valley, California, but is now at Fairview, Nevada.

T. H. JENKS is in Gunnison county, Colorado, but will shortly return to his Denver office.

F. LYNWOOD GARRISON is at Kimball, Nevada, and will be in San Francisco about November 15.

EDWARD HIGGINS has returned to Los Angeles from a professional trip through Arizona and Sonora.

W. H. TREWARTHA-JAMES, general manager for the Tyee Copper Co., Victoria, B. C., is visiting New York.

W. H. HUTCHINS has resigned as superintendent for the Whitman Mining Co. at Pearl, Idaho, and is at Boise.

C. O. MOSS has resigned the position of superintendent for the Sierra Morena M. & R. Cor., Paso Robles, California.

J. NELSON NEVIUS has been appointed consulting engineer for the company operating the Dixie Meadows mine, near Sumpter, Oregon.

FRANKLIN W. SMITH has been made consulting engineer for the Palmilla mine at Parral, Mexico, with T. N. STANTON as mine superintendent.

H. V. WINCHELL delivered an address on the Stockholm meeting of the International Geological Congress, before the Minnesota Academy of Science, December 6.

WILLIAM A. FARISH, JR., of McLennan & Farish, has completed the organization of mine work and installation of machine-drill equipment at the Keane Wonder mine.

D. C. JACKLING of Salt Lake, N. B. MCKENZIE of New York, and A. H. FITCH of Kansas City, members of a party of capitalists who are interested in copper investments in California were in San Francisco this week.

DAVID COLE, assistant manager for the Cananea Con. Copper Co., has resigned to accept the position of general manager for the Ray Con. Copper Co., Ray, Arizona, the change to take place January 1.

C. C. DERBY was in San Francisco this week. He has resigned as consulting engineer for the Sturgiss interests on the Comstock Lode and will open an office at Nevada City for consulting work.

W. A. D., Landlock Bay, Alaska: Quartzite.

R. P. A., Ely, Nevada: Quartz with manganese dioxide.

J. H. W., Luning, Nevada: Quartz stained with iron oxide.

A. G. McD., Kamloops, British Columbia: Sandstone with limonite.

B. F. N., Ocampo, Chile: No. 2, quartz rhyolite; No. 3, arkose; No. 4, rhyolite.

H. L. R., Cornucopia, Oregon: No. 1, feidspathic rock with graphitic matter. No. 2, diorite.

TIN STATISTICS

L. Vogeistein & Co. report tin statistics published December 1 as showing Straits shipments of about 4800 tons and United States deliveries of 3800 tons. Total supplies exceeded total deliveries and visible supply was expected to increase 1000 to 1500 tons. Considering that this is the dull season of the year and especially in view of the adverse conditions under which the trade in this country has labored, results may be regarded as quite favorable and a good business has been done at advancing prices. Up to December 1 United States deliveries in 1910 increased 3450 tons as compared with 1910; Straits shipments decreased 2400; visible supply decreased 1000; price increased 5¾c. per pound. The rise in price has apparently discounted the improvement—the position alone considered—but the outlook is for continued good demand, moderate supplies, and further shrinkage in visible stocks.

JOPLIN LEAD AND ZINC PRICES

A review of the Joplin lead and zinc market for the week ended November 26, shows that the highest price paid in the district for zinc sulphide ore was $51 per ton, on a base price of $48 per ton of 60% zinc; zinc silicate ore sold on a base price of $24 to $27 per ton of 40% zinc. The average price of zinc ore of all grades was $44.94 per ton. The highest paid for lead ore was $58 per ton, the average of all grades being $56.32 per ton. For the first 11 months of the year zinc ore shipments showed a decrease of 2838 tons, and the lead ore shipments a decrease of 1971 tons from those of the corresponding period last year, the total value of those shipments showing a decrease of $552,113. The shipments for the week from the district were as follows: zinc, 10,002,240 lb.; lead, 1,455,980; total value, $265,784. For 11 months ended November 26: zinc, 540,092,370 lb.; lead, 76,333,670; total value, $12,735,308.

COMMERCIAL PARAGRAPHS

The Edgar Allen American Manganese Steel Co. announces that Walter Brinton, superintendent of the manganese steel department of the Taylor Iron & Steel Co.'s plant at High Bridge, New Jersey, since 1895, has resigned and has accepted a position as consulting engineer for the Edgar Allen American Manganese Steel Co. Mr. Brinton's headquarters will be at the New Castle plant.

The Denver Fire Clay Co., Denver and Salt Lake, has recently put the Donaldson tilting furnace on the market. It is a simple and efficient device for melting and refining cyanide precipitates, gold and silver bullion, brass, copper, lead, and foundry metals. It is made in three sizes and may be adapted for using either gasoline or city gas as fuel. A bulletin descriptive of this furnace has been issued by the makers and is now being distributed.

F. G. Bolies, commercial engineer for the Allis-Chalmers Co., has resigned in order to devote his entire attention to The Reliance Engineering & Equipment Co., 1417-19 Majestic building, Milwaukee, in which he has an equal interest with C. A. Tupper and others. The company, which is taking on a number of additional exclusive agencies, will remove December 1 to rooms 415, 416, and 417 in the new Engineering building, and considerably extend the scope of its operations.

CATALOGUES RECEIVED

American Well Works, Aurora, Illinois. Bulletin No. 118. 'Irrigation by Pumping.' Illustrated. 32 pages. 8 by 10½ inches.

Joseph Dixon Crucible Co., Jersey City, New Jersey. 'Graphite Products for the Railroad.' Illustrated. 44 pages. 5½ by 9 inches.

A. Leschen & Sons Rope Co., St. Louis, Missouri. A pamphlet intended to "provide a means by which a quick selection of quality and construction of wire rope for service other than ordinary may be made without consulting the manufacturers." Illustrated. 24 pages. 5 by 7 inches.

Hayward Digging Machinery. Being catalogue No. 38 of the Hayward Co. of New York. Illustrated. 78 pages. 9 by 12 inches. It is seldom that a more handsome trade publication than this is issued. The illustrations are unusually excellent reproductions of photographs and portray faithfully the many industrial uses of 'digging machinery' as applied to dredging, mining, trench-digging, and the handling of materials. The descriptive text is wholly subordinate. An interesting feature of the catalogue is the fact that the illustrations are from the field rather than the shop.

The Stromberg-Carlson Telephone Mfg. Co., Rochester, New York, has lately re-issued its Bulletin No. 1000 on 'Mine Telephones.' The value of telephone service in mines is coming more and more to be appreciated by operators. Aside from the convenience to managers and superintendents, the added safety which instant communication with all underground workings affords to the miners themselves

makes the installation of a telephone system a necessity rather than a luxury. The expense of equipping a mine with telephones is comparatively small, due to perfection of simple apparatus and standard equipment. The illustration herewith shows the standard type of instrument for underground use as made by the Stromberg-Carlson Telephone Mfg. Co. It is contained in a moisture and gas proof cast-iron box. A special feature is the 'cord take-up' device by means of which the cord on the receiver is automatically taken up when the latter is replaced on the hook. Other interesting features of these telephones, wiring diagrams, and list of mining companies using the Mine-A-Phone system are included in Bulletin No. 1000.

TABLE OF CONTENTS

EDITORIAL

GRANBY CONSOLIDATED has adopted a policy of complete publicity and is now issuing monthly statements of production. The October statement showed 1,184,234 pounds of copper shipped, with $70,092 worth of gold and silver.

AMERICANS are taking an active part in development of the Orient, especially in placer mining. Mr. James J. Martin has just been engaged to develop rich gold placers recently found by the Collbran-Bostwick Development Company near Kapsan, Korea.

EXTRA-TERRITORIAL RIGHTS of foreigners in Korea have not been lost, as has been decided in a test case at Seoul. They are likely soon to disappear, since existing foreign treaties covering the subject expire January 1, except that with the United States. The American treaty extends till 1912. By that time the new régime should be in smooth working order.

CRIPPLE CREEK is already feeling the benefit of the Roosevelt deep drainage tunnel, as is noted in our news columns. Another factor making for prosperity there is the milling of low-grade ore on the ground. The New Portland mill and the Stratton's Independence plant are forerunners of others that will handle ore long sent over the dump. Progress in treatment of Cripple Creek ores was recently discussed by Mr. Philip Argall in an address reprodneed upon another page. It will be read with much interest and Mr. Argall is to be congratulated on the starting of the second unit of a great mill.

WHEN Mr. Hoke Smith was Secretary of the Interior he decided that oil was not a mineral. Congress promptly overruled him by enacting that none the less oil land should be taken up under the law provided for placers. Whatever may be said for the theory of the matter, it is now fairly clear that it would have been better not to have attempted to treat oil legally as a mineral. In Ontario it has just been decided, as related in our Toronto letter, that while oil is a mineral, natural gas is not! In arguments over the Indiana gas cases we believe it was held that while gas was a mineral it was at least strongly analogous to wild game and therefore its shipment outside the State could be legally prohibited. All this is doubtless clear to lawyers, but to engineers it would seem simpler to recognize the nature of materials and frame laws accordingly rather than to depend on analogy and fine-spun construction of fundamentally inapplicable laws.

CONGRESSMEN are discussing a committee on committees in the House of Representatives in place of allowing the Speaker to exercise "arbitrary" power in the matter. We seem to have heard of such a committee in the Senate with Mr. N. W. Aldrich as chairman, and yet reformers appear not to have been altogether happy in that body.

State Geologists

Nearly every State in the Union now maintains an organization devoted to securing the wise development of its natural resources, and particularly its mineral wealth. Whether it be called a Geological Survey, a Bureau of Mines, or a Department of Natural Resources, the main purpose is the same. Departing slightly from early ideals, these organizations now place large emphasis upon the maintenance of an information office; a place where intending investors, land owners, and others can get information and free advice likely to assist them in finding materials or markets. Where the work is done by honest and capable men returns have been large, but it is essential that the bureau have the confidence of people with whom its officials come into contact. It may be either his fault or his misfortune if the head of such a bureau finds that his statements are considered inaccurate or his advice interested. In either case his usefulness is ended. A statement that is doubted is not convincing and advice from an interested person is heavily discounted. The head of such a bureau should be not only convincing but honest. His reports are sure at some time to be read by some one who knows. Officers of the United States Geological Survey are prohibited by law from doing any private work or having any financial interest in the territory under survey. The same rule should obtain in the case of corresponding State officials. It is unfair to other engineers that such an officer should compete with them for the business of making examinations and reports. A more serious objection is that companies will hesitate, and properly, to give such an official statistical and other technical details, if any chance exist of their being turned over for a fee to a competitor. The State should pay enough to warrant the undivided loyalty of the chief of such a bureau. If it does not do so he should none the less abide faithfully by the terms so long as he choose to remain in office. To do otherwise is to limit the usefulness of the position and has, in cases, threatened the continuance of the work. It is axiomatic that no such position should be in politics. The officers of such a bureau should be selected on the basis of fitness, not because of their ability to 'swing a delegation' or 'carry a ward.' If the position is to be political it is better to be open and frank about it, as in Indiana, where the State Geologist is elected by popular vote along with the Governor, the Auditor, and Justices of Peace and town Constables. It occasionally happens even under such a system that a good man gets the office, as was true in the case of Mr. W. S. Blatchley. He, however, is to retire next month because the citizens of Indiana were dissatisfied with the new tariff law enacted at Washington. Much the better plan, and the one commonly adopted, is to place the control of the bureau under a non-partisan commission that is usually partly, if not wholly, ex-officio. It is customary in such a case for the Governor and the president of the State University to be members of the board, and this works well in practice. Any plan is good that assures appointment of capable men and the doing of honest work. When these are secured there is usually no trouble in getting a moderate allotment of funds with increases as the work justifies itself. In several States new appointments are to be made early in 1911 to positions on such boards or, where there is no commission, to the position of head of the bureau itself. We would like to urge in the strongest possible terms that in the selection among candidates, fitness only be taken into account. Men of character having technical knowledge and practical administrative ability should be appointed. It is not always easy to find such a man ready to take the place, but if the office be given a chance to seek the man, a suitable person can be found.

Traveling in Africa

Boyhood, like Boston, we are persuaded, is a state of mind. And blessed is he who keeps the spirit of adventure however much he may grow up in his profession. Since the days when with Mayne Reid we 'Ran Away to Sea' or, safe from discovery comfortably stretched out on the floor of the 'best room' we breathlessly followed Stanley in his search for Livingstone, Africa has had a strong attraction for us. Of recent years our enthusiasm has been somewhat dampened by the evident fact that South Africa was becoming civilized, while tales of the impossible climate of the West Coast urged a bit of caution when the spirit of the explorer threatened to become irresistible. Mr. F. F. Sharpless has, however, let loose all the old longing. Who wouldn't be a mining engineer, if he could go to Africa and be received in each village with 'dashes' of chicken presented by a 'head man' or king? It is true a possible sinister double meaning hangs round the first title, but that may well be but an astral notion due to early reading. Mr. Edgar Allen Forbes has told us in recent numbers of *The World's Work* that guides are not necessary in Africa—except to protect the traveler from other guides—and doctors assure us that with boiled water and quinine we may defy the most voracious microbe. The doctors, in fact, are taking all the danger out of trips to tropical countries. Mr. Howard Smith, who recently visited French Guinea, suffered most from cold while crossing the mountains in a railway train, and bought canned California fruits within two days of Timbuktu. At Konakry the French doctors had fought fever so successfully that, like Thomas Hardy's sheep dog, they had nothing left to do; the excellent hospital at that point being without a patient. The conquest of the tropics by the men of the north is one of the great achievements soon to be credited to human endeavor. For it, the doctor and the engineer will divide credit. Mr. Sharpless is to be congratulated upon having

seen the work in progress, and our readers on having had his cheerful account of the trip. The lesson is obvious. Keep young in spirit and you will enjoy your work, and by enjoying it, will do it better.

The President's Message

The message submitted to Congress December 6 by Mr. Taft, is a plain business document in which the activities of the Government are reviewed, much as the president of a large and prosperous corporation would present a résumé of the year's business to the directors and stockholders. And it is as worthy of being read by each citizen as if the latter were an ordinary stockholder anxious to know what further assessments would be needed to put the enterprise on its feet. The United States Government is in fact an enormous business enterprise, and it is not easy to get an intelligent idea of its income, its expenses, or its work. The President evidently has faithfully studied the reports and recommendations made to him and has succeeded unusually well in digesting and building upon them a systematic, consistent plan. The message is too long either to produce or summarize. We can only touch upon a few points of especial interest to mining men.

The laws relating to mineral lands, excluding coal, oil, and phosphate lands, the President considers to have worked reasonably well. While in his judgment the doctrine of extralateral rights is vexatious and should not have been incorporated into the law, he feels that any change now would do more harm than good; a general though by no means universally held opinion among mining engineers, it may be remarked. So too, he suggests, while it might have been well in the beginning to have leased rather than sold all mineral lands, the time for such action has passed except as noted. For coal, oil and gas, and phosphate lands he considers special reasons to exist that warrant a change now to the leasing system. In brief these reasons are that a large part of the whole amount of coal and phosphate remaining unmined is on Government land and the same is thought to be true of oil and gas. In order to secure economical development, proper conservation, and to restrict monopoly, he believes that a closer control should be exercised over these lands and that the substitution of a leasing system for sale will permit fair solution of these problems. The difficulties involved are frankly met and the President suggests that while at first it would doubtless be necessary to give the executive rather wide discretion as to terms of leases, these terms should be made statutory as rapidly as possible. In general, control rather than revenue should be sought, though a royalty neither greatly over or under the rate imposed by private owners should be exacted. The rate should be readjusted at fixed periods, the terms of the leases should be long, the areas leased sufficiently large to warrent investment, the bids competitive, and, specifically in the case of gas and oil, exclusive prospecting permits for two years should be issued upon application and payment of a small sum. In the case of phosphate land, the Government should reserve the right to forbid exportation of the material mined. Such in outline are the plans proposed by the President after hearing arguments on both sides, and such evidently it will be his effort to have enacted into law. The changes proposed are sweeping and are radical when viewed in the light of the historic American policy of giving land freely to any one who will use it. The change is not, however, greater than was made in the various Australian States and the proposed system is one already in operation in many parts of the United States. Indeed if it be adopted the Federal Government will be but taking advantage of the experience of private land owners and of certain American States, such as Minnesota and Colorado, which now lease rather than sell mineral lands. The plan is not even as broad as that adopted by the States, since the latter lease metalliferous lands, while Mr. Taft only proposes to apply the system to certain non-metalliferous minerals.

In regard to Alaska the President reiterates his recommendation of a commission form of government, pointing out that the population is not only scattered but migratory. He does not believe in extending financial assistance to secure building of railways, but is strongly of the opinion that the coal-land laws should be modified so as to encourage the opening of mines. This, he believes, will be sufficient to induce the completion of projected lines and building of others. While strongly believing in the feasibility as well as necessity of controlling water-power development, he leaves to Congress without recommendation the question whether this should be done directly by the Federal Government or by the State acting as trustees.

All these recommendations are prefaced by a full and candid consideration of the arguments for and against each, and his conclusions are backed by detailed statements as to existing conditions. It is evident that Mr. Taft values special knowledge. He recommends the creation of a number of expert commissions and quotes freely from those who have made particular studies of individual problems. Mr. A. H. Brooks is quoted as to Alaska, Mr. C. W. Hayes as to Panama, and Mr. G. O. Smith as to several things. As would be expected from his past service as Secretary of War, Mr. Taft places a high estimate on the opinions of the Army engineers. We are sorry to see that his references to reclamation do not do justice to the able engineers in the Reclamation Service. Throughout, the message is conservative. He evidently holds strongly to the opinion that the country has reached a stage where additional changes in the law should only be made with great caution. The keynote of his message is the closing sentence: "It is in the interest of all the people of the country that for the time being the activities of the Government, in addition to enforcing earnestly and impartially the existing laws, should be directed to economy of administration, to enlargement of opportunities for foreign trade, to the conservation and improvement of our agricultural lands and our other natural resources, to the building up of home industries, and to the strengthening of confidence of capital in domestic investment."

Visiting the Gold Coast, West Africa

By F. F. Sharpless

The article in the *Mining and Scientific Press* of September 10, by J. A. MacDonald, and his comments on the viewpoint of a traveler in a rough country are entertaining and call to mind a recent experience on the West Coast of Africa.

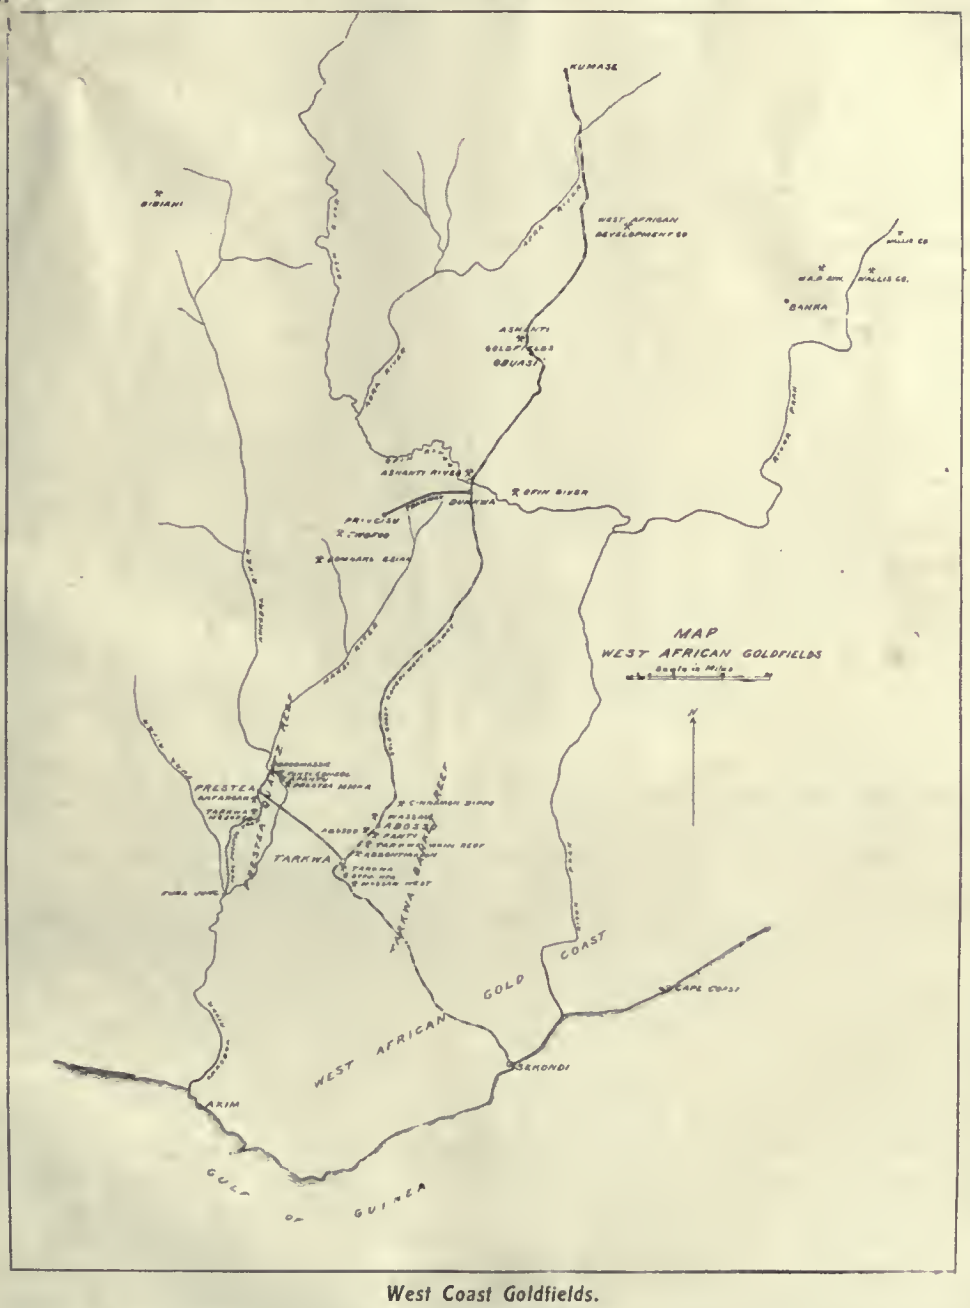
"No, thank you, none of the West Coast for me," would be the answer given by a large majority of Americans if asked to go to that country. Ever since gold in the West Coast has been sought, stories of an impossible climate, a country pregnant with disease and hardship, a country to which many white men went, but from which few returned, have been common. It is a bad country. Many of the stories are true and give a bad impression, but mainly because they do not tell all of the truth. I confess that it was with some misgivings that I took steamer for the Gold Coast, in January 1910. The anticipation of sickness in a foreign and little known country added no grain of comfort to a rough passage in a small steamer across the Bay of Biscay, and at that time I had little thought that I would some day look back upon the trip as one full of interest from start to finish—one full of interesting and pleasant experiences, and almost as free from disagreeable incidents as though the trip had been made in one of the more sparsely settled districts of our own continent. The steamers from Liverpool to the West Coast are small, slow boats, and as there is but little competition for the passenger traffic, accommodations are not of trans-Atlantic steamer quality. They, however, compare favorably with those between North and South American ports. It is on the steamer that the traveler's interest is first aroused in this part of the 'Dark Continent.' He is thrown into intimate contact with men who have lived for years in the country. Some are inclined to paint the horrors of the jungle in somber color for the benefit of the tenderfoot, especially if he is inclined to show the white feather, and many a poor chap has landed and started for the mines feeling sure he had seen the ocean for the last time. But it is also on the steamer that there is opportunity for talking with government officials who are spending the greater part of their lives on or near the coast. These men, as a class, are intelligent courteous fellows, ready to tell what they know of the people and the country in which they live, and many a pleasant hour may be spent listening to experiences of themselves and of others in this strange land. On the steamer one is able to learn in a short time, much respecting the native customs and habits, their beliefs, their superstitions, and their religions; if, indeed, they have anything that can be called religion. Then there are almost sure to be on board mining men who have been in the country before, and from them one may learn much of interest respecting the business that is calling him to the country. Short stops are made at the Canary Islands and at Sierra Leone, but the two weeks on the steamer slip away quickly and Sekondi is sighted before the voyage has become wearisome.

Sekondi, or Seccondee, is the port of entry for nearly all of the mines. The European portion is clean, and attempts to keep the native quarter in the same condition have been fairly successful, but the presence of many stagnant pools, lack of good fresh water, and the very nature of the black man are all against ultimate success or perfect healthfulness. Fever is always present and probably always will be, but it is not bad for a Coast town, as one learns if he has occasion to visit others where there are fewer white men. Sekondi boasts the one hotel that is to be found in the whole of the mining district, and after this is left behind the traveler must depend upon the courtesy of the white men he meets and upon his own servants. As a matter of fact, the first thing after landing is to look up a good cook and a black steward boy, indispensable accessories of an outfit if much of the country is to be seen. The steward boy acts as interpreter, is head boy among the carriers, looks after the traveler's personal wants, buys his railway tickets, attends to the baggage, the hammock, the bath, and stands at 'attention' for all odds and ends. On landing at Sekondi I was soon spotted by a black man who had an important matter on his mind. For some time I could not understand his language, but after a time it dawned upon me that he was talking English, and was informing me that he had been sent to act as my steward boy during my stay in the country. I feared for a while that I would have to employ an interpreter to tell me what my interpreter had to say, but by degrees I learned his English, and he learned mine, so that we got on fairly well. This boy followed me like a dog all over the country and did his best to take good care of me. A few nights after landing we were stopping with the manager of an English trading company. I had retired early and was awakened from a sound sleep about midnight by peculiar motions of my bed. Presently I thought I could hear some one breathing; reaching out, I turned on the electric light, but no one was in sight. Looking under the bed, I was astonished to see a big black thing coiled up there in the 'all together,' fast asleep. It was my steward boy. Asking him in the morning why he slept under my bed, he replied, "I no savey the black boys in zis Massa's bungalow. I look you well (I must take good care of you). I sleep your bed."

Leaving Sekondi by the early morning train, for which privilege one pays a very liberal retainer, our way led through a tropical jungle for some hours. There are a lot of native villages along the railway track, and a large percentage of slightly clad natives, children predominating, indolently watch the train go by. There are a few plantin farms on either side of the track and a little corn, but every day is Sunday with most of the natives, and little work supplies all their wants. So why should they work? About nine, I reached the town of Tarkwa, or Tarquah. Whe Weste Coast is a paradise for one weak in orthography. Spell any word the way it sounds to you, and no one can say you

are wrong. To be sure it is a little inconvenient sometimes; your letter or telegram may be sent to the wrong town, but that is not your fault.

Tarkwa is the first large village reached on the railway. It is in the centre of the mining district, and from it supplies are sent out over the entire field. At Tarkwa, if not accredited to any particular mine, you will probably be met by Mr. Auerbach, or Mr. Abraham, managers of the Tarkwa Trading Co., or



West Coast Goldfields.

by one of the clerks of this most hospitable establishment, and from this time forward you will have few troubles because of being a stranger in a strange land. Here you will receive suggestions and help in regard to outfitting both as to supplies and carriers. You meet the managers of the local mines, and you meet the government men, all of whom are courteous and kind, ready to give you whatever help or assistance you may require. So pleasant do they make it, that some of us found it hard to tear ourselves away for the rather more strenuous life of the bush. Tarkwa is directly over one of the bankets that is being successfully operated, and a few days spent underground at the nearby properties give one a fair idea of the characteristics of the formation at this particular point. However, it will not do to draw the conclusion that all of the commercial ore has the same appearance and that knowing it at Tarkwa, the engineer will know it wherever he sees it. The area over which banket (a coarse sandstone or conglomerate) occurs is large and many croppings are found, but even after a most intimate acquaintance with the Tarkwa banket no one can hazard a guess at its contents without panning or assaying. After a week or ten days at Tarkwa, it is advisable to visit the Prestea formation for an equal time. Here the gold is found in quartz veins and these promise to be of equal commercial value with the banket deposits, indeed, it looks just at present as though they might, for a time, outstrip the latter in production. When the visitor has familiarized himself with conditions in these two districts he is ready to take to the bush and examine some of the prospects and less developed properties. Bush traveling is an experience worth having at least once, and if made in company with an experienced traveler, or if outfitted and properly started by some one who knows, there is much of pleasure and interest in such a trip. For two weeks or a month in the bush about twenty carriers will be found necessary. Of these eight should be good hammock boys, the rest may be boys or women, whichever are more convenient to secure. There are no beasts of burden in the country except the black people, because of the presence of the tsetse-fly, hence every traveler is accompanied by a small army of black followers. Of the outfit, a bunch of good hammock boys and a comfortable hammock are most essential. Walking is possible everywhere, and while the unencumbered traveler can easily outwalk his loaded carriers, he should not waste his strength unnecessarily. In addition to the hammock boys, there must be carriers for the 'chop' boxes, cooking outfit, clothing, bed, chair, table, bath, and any prospecting tools that may have to be carried. Chairs, tables, and baths may sound rather luxurious, but they are as much necessities as the chop box. The

daily bath, with plenty of fresh clothing, a comfortable steamer chair, a little camp table, and a well stocked chop box are not absolute necessities. You can get through the country without them, but don't try it. You have enough hardships, and these apparent luxuries mitigate the rougher experiences, giving one the impression that he is having a pleasure trip and make him fit for the real hardships when they do crop up. My first trip was taken along the railway. I wanted to get my outfit and myself broken in by a short trip. That was the first big blunder that I made; it was only a six-mile walk down the railway and then a mile into the bush, but the trip was started at 2 p.m. Hammock boys are of no use along the railway; they require a good foot-path, wide enough for two men to walk abreast, so that one end of the hammock may be carried between them. The consequence was, on this occasion, that I walked the six miles down the track in the broiling sun. The West Coast sun knows how to broil, and with the trees cut for 100 ft. on either side of the track, it gets splendid action on the man that ventures out in the sunshine at noon. It is the sun and alcohol to which may be attributed the long death roll on the Gold Coast. The amount of alcohol absorbed by many white men on the West Coast is large, so large that in any country the amount would be considered dangerous, but when here, loaded to the limit, a man goes out at mid-day and gets the full benefit of the sun on his head and spine, he has a strong hold on life if he lives long. The little six-mile trip taught me some lessons, and when I started out the next time, I saw to it that any tramping in the sunlight was done in the early morning, or late afternoon. Away from the railway one soon plunges into the forest, and it may be that for half an hour at a time he will scarcely see the sun; it is only as villages are approached and the plantations around them are entered, that one is forcibly reminded of the existence of the sun, and takes to his hammock regardless of the condition of the trail. Starting out in the early morning, the traveler generally walks for several miles, or for an hour or two. By that time he is ready for a dry shirt and a ride in the hammock. He continues in the latter most of the day except when the trail grows too narrow or too rough for easy carrying, when he takes to foot and gives his boys a rest. Villages along the trail are passed at frequent intervals, giving one the impression that the country is thickly populated, and that laborers are plentiful. But unfortunate is the traveler who has occasion to hire a few men along the way. He will find that "all of the workers are out on the farms," or "they are sick," or his "bundles are too big," or he is "going too far," or "there is nothing to eat" where he is going, or they "can't go until they have had chop."

One of the important 'don'ts' is, don't leave your base of supplies without taking all of the men you need and to spare. They are a happy lot of creatures, both your carriers and the people of the villages through which you pass. There is continuous chatter and laughter all day long among your followers, and nearly always a pleasant reception in every village passed. Stopping for lunch near a village, you generally find it ready to feed your boys for a small consideration, and to furnish you with eggs or chickens, if there are any. At night the custom is for the traveler to stop at one of the more prosperous villages. His steward goes to the head man, chief, or king, as he may be called, and asks for the best house in the place. A house is selected, the owners move out, it is swept out, and the traveler's outfit deposited. Many of the villages are clean, and I found this method of getting on much more satisfactory than carrying a tent. Chickens, eggs, and vegetables are nearly always to be found, and these are used so far as possible, sparing the chop box until a more unfortunate day. Your native provision is generally given or 'dashed' you, and by return 'dashes' of sugar, candles, or coffee, you pay a fairly good price for what you get. On the trail your water bottle is something to be remembered. Don't part with the water bottle and its boiled water on any pretext. This was forced home to me one day when I was walking for a little while. I was in a country where the trails were unknown to my porters. After an hour and a half walking I realized that we had lost the trail and were in for a long tramp to return by the way we had come, or a short and hard tramp through thick jungle to get back into the proper trail. We took the latter course, but didn't find the cut a short one. We were four hours getting back to our trail, four hours without water and with violent exercise, taught me to be careful about that water bottle on subsequent trips. Traveling at night is spooky work. At night the boys are quiet, and as the party tramps through the forest nothing is heard but the dull patter of the bare feet on the smooth trail. An occasional owl hoot is in harmony with the surroundings, and the maniac yell of the flying squirrel close at hand, starts a shiver as you wake from a doze in your hammock. The real work in traveling is off the beaten trails. When it is necessary to do any prospecting, or make examinations of old native works, trails must be cut for every foot of ground covered. You must be right up with, or ahead of the boys with the cutlasses, and you are working harder than they all of the time. Left to themselves the boys spend much time in resting, and have a way of making paths in most every direction except in that in which you wish to travel. Time is not an important factor with the native, and the foreigner does well to allow himself a large margin of safety when calculating the number of days he will devote to a given piece of work.

Leaving the country is always a pleasant and sometimes an interesting part of the trip. I had finished by last examination and had returned to the railway ready to take the train the following morning to my headquarters; the steamer was to leave a few days later. About 10 o'clock I was awakened from my first doze by the native station master who brought me a letter. I didn't care particularly for a letter then, but out of curiosity opened it, to learn that the port was closed because of yellow fever, and that no steamers would stop until further notice.

My dreams were not pleasant that night; indeed, I do not remember that I had any dreams at all, I was quite fully occupied with wondering how I was going to get out of that country. My work was finished, my outfit disposed of, my boys scattered. There were other ports, but they were many days away and might be closed by the time I could re-equip and reach them. I was fortunate in finding near at hand a camp where I was hospitably taken in and allowed to loaf for a few days until the worst of the scare was over. In two weeks a village near Sekondi was officially declared clean, and steamers were permitted to take passengers from it. The night previous to the sailing day found several of us on hand with our baggage, which fortunately included bedding, and it was also fortunate that it was after dark when we reached the village, Chama by name, an old coast trading town. Had we been aware of all the dirt around us, and yellow fever known to be only six miles away, our slumbers might have been anything but restful. As it was we slept in comfort and in ignorance and at 10 next morning had the pleasure of seeing steamer smoke on the horizon. About the same time a party of Europeans, something more than a score, who had been in quarantine for two weeks at Sekondi, arrived. They were more anxious to leave the country than we, and immediately engaged all the surf boats in sight and started for the smoke. By the time the steamer had reached its anchorage two miles from the shore we were ready to go out, too. Our head boatman, however, informed us that the steamer just dropping its anchor was a freight boat and that ours might be the one that was just then showing smoke on the horizon. He further advised us to take our baggage out of the boat and put it under cover and not to go out for a while, as it looked like rain. We were wise enough to adopt the suggestion of the old boatman, and our baggage was just safely put away when a hurricane broke over us and for two hours lashed the shore with wind, rain, and waves, while we sat and wondered what the boys on the water were doing.

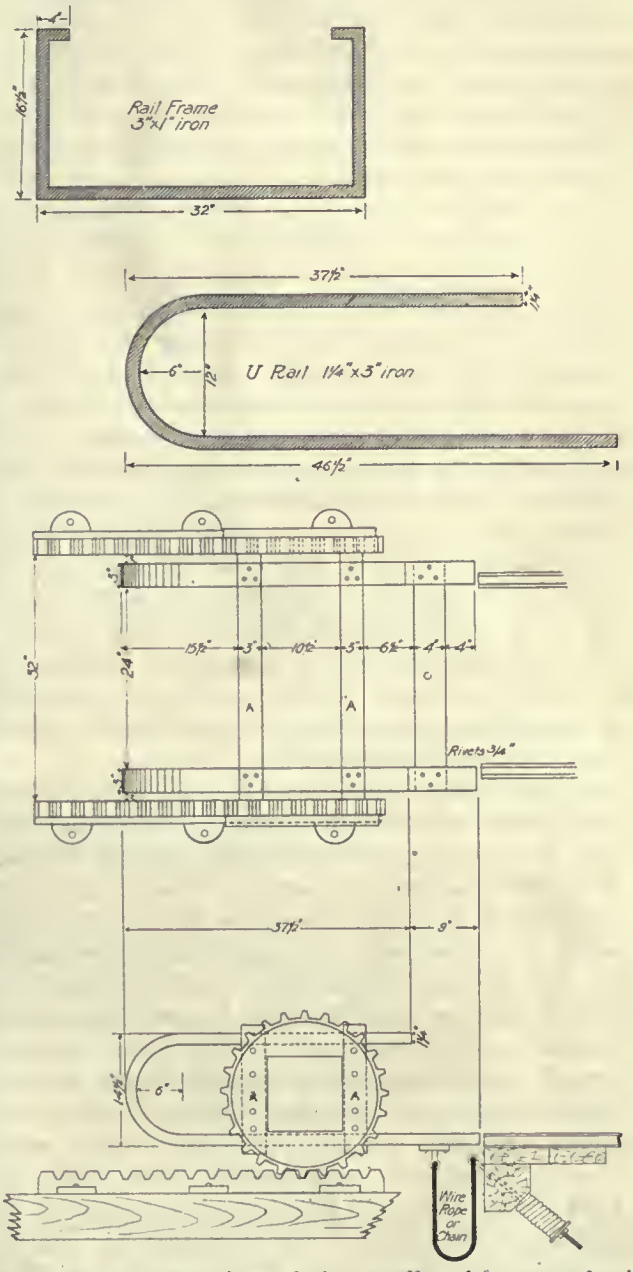
Our boatman finally came and advised us that it was safe to go out and that our steamer was now waiting us. It was rather a rough passage, but a pleasure trip in comparison with the experience of the first party. The white men in each of the canoes had been bailing with their helmets and hands; three of the canoes had turned over and emptied their contents into the sea. The men in them had been saved, but minus their belongings. Speaking with one of the unfortunates later he remarked, "Well, I had the time of my life, but I am glad it's over." Some of my readers may have an opportunity to go to the West Coast. My advice is, don't expect a pleasure trip, don't take your wife, and don't fail to go if you get a chance. It is fully worth the little inconveniences that you must suffer.

Nuggets of hornsilver were picked up on the slope of Antelope hill, southern Yavapai county, Arizona, in 1890, but no large deposit or vein of the mineral was found in the vicinity.

CRADLE FOR DUMPING MINE-CARS

By S. S. Clarke

The accompanying sketches illustrate the type of cradle used by several companies in Madison county, Missouri. While many operators may be familiar with this type, there will be others to whom it is new and some benefit may be derived from a description of it.



In the construction of the cradle, the gear-wheel and rack-rail are made of cast iron, the gear usually being chilled, while gray cast answers for the rail. Two rail frames A, of 3 by 1-in. iron, 52½ in. long, bent as shown, are riveted to the gear-wheel with eight ¾-in. rivets. The **U** rails consist of two pieces of 3 by 1¼-in. iron, 7 ft. 9¾ in. long. These are riveted inside of the rail-frame, the distance between the rails being the same as the gauge of the track. The measurements given are for a cradle handling a one-ton car with a 24-in. track gauge. The curve of the **U** rail is governed by the radius of the car-wheel. A stout spring fastened with an eyebolt to a timber and connected to the cradle by means of a chain or wire rope, will right the cradle after dumping the car.

Cyanidation of Cripple Creek Ores

By Philip Argall

*We are here tonight to help celebrate the successful starting of the second unit of Stratton's Independence mill. We thus reach an important point, not alone in the history of our own mine, but also in the history of the Cripple Creek district; the pioneer work is accomplished and wet-milling of $3 sulpho-telluride ores established as a profitable industry, away up here in the mountains where milling supplies are charged all the traffic will bear. Most of you have contributed, in one way or another, your knowledge, strength, and experience to help obtain this great result; though several of those who started out with us in the summer of 1907, in what was then called by hotel experts and club loungers 'the metallurgical impossibility,' have moved to other scenes and assumed new responsibilities while others again have but recently joined our ranks. To these younger men we look with expectant interest, for new ideas and for renewed energy which may lead to greater efficiency in all departments. At such a time as this one may be pardoned for pausing in retrospective mood to view again the point from which he journeyed and perhaps push the tentacles of thought out into the uncertain future, to see in vision, as it were, the ultimate metallurgical destiny of wet-milling the sulpho-telluride ores of Cripple Creek.

Eighteen years ago I first became interested in cyanidation and soon thereafter accepted the position of consulting engineer to the company holding the McArthur-Forrest patents for America. I made my initial trip to Deadwood, South Dakota, to examine into unexpected troubles that cropped up in the first cyanide mill built in the Black Hills, the ores of which were so favorable to cyanidation. The first mill erected was for a time a failure and but few, if any, foresaw the brilliant future for the cyanide process in that great mining district. My second trip was to Cripple Creek, where a small cyanide plant had been erected, later called the Brodie mill. This mill failed to give the results expected, as had also the one at Deadwood, and for precisely the same reason. The ore after grinding could not be leached. Improved crushing machinery, however, solved the problem in both cases, and the Brodie mill struggled along for some time at a capacity of 15 tons per day, later raised to 30 or 50, and ultimately, I believe, to 100 tons per day. In the spring of 1894 we had no difficulty in procuring a full supply of ore for the Brodie mill of about one ounce value per ton, for which the mill received $15 per ton treatment charge and needed every cent of it. My connection with this mill, though short, was ample to convince me that cyanidation had a great future in the metallurgy of Cripple Creek ores. I consequently experimented quite extensively with the telluride ores and, in fact, worked out, wrote up, and published the identical method of treatment now in use at Stratton's Independence mill. I proclaimed the cyanide process to be the most suitable all-round method for treating Cripple Creek ores, a thesis I stoutly maintained with tongue and pen against all comers, until the use of cyanide became universal in the milling of Cripple Creek ores.

The fall of 1904 found me engaged in building the first large custom mill for the direct cyanidation of telluride ores, while the following year I introduced roasting as an important step in cyaniding sulpho-tellurides. The Metallic works, also a pioneer in Cripple Creek metallurgy, ultimately reached a capacity of 10,000 tons per month, and at the close of my engagement, January 1901, had treated almost half a million tons of Cripple Creek ore, mostly by the roasting process, and had from the first earned good dividends on the investment, and this in the face of a steadily decreasing treatment charge.

From my first connection with Cripple Creek milling, to the close of 1900, the average treatment charge had been reduced 50 per cent, and it must be conceded that the works of the Metallic Extraction Co. was an important factor in this great reduction. Were I relating a personal narrative, or holding forth on my varied experience in cyanidation, I would next direct your attention to Mexico, to Canada, and to other countries. I am, however, merely tracing the progress in cyaniding Cripple Creek ores and incidentally, though briefly, noting my own pioneer work in that connection. Suffice it to say, then, I returned to this field of activity in 1906 and early the following year took up the greatest ore-treatment problem of my life. To understand it clearly, it might be permissible to say that at the Metallic Extraction Co.'s works near Florence, where fuel and general supplies were reasonable, the climate mild, and water abundant, I had gotten the ore treatment cost down to what I then considered a low figure. The problem involved in Stratton's Independence dump, however, contemplated the profitable treatment of an ore—including mining it in the dump and conveying it to the mill—the total value of which was less than our average cost for treating a ton of ore in the Metallic works in the year of grace 1900. Here, then, was a problem of some magnitude and I will frankly admit that it was only the quantity available in the dump, something like a million tons, that induced me to make the attempt. Roasting was out of the question on account of the cost; so I went back to my old concentration tests of 1894, and found that modern concentrators and fine grinding gave very encouraging results. A long series of experiments proved to my satisfaction that 35% of the gold value could be removed as concentrate from average dump ore, and, strange to say, cyanide was good for a similar percentage. Next came the cost of the method, to determine which I had to draw on previous experience in concentrating and cyaniding on a large scale. Finally, having proved my experimental work in all particulars, I cabled the company in March 1907, that a mill of 10,000 tons monthly capacity could

*Address at banquet in celebration of the first month's run of the second unit of the new Stratton's Independence mill.

treat the dump ore by the proposed method at a cost of $1.50 per ton, obtaining a yield of 70% of the contained gold. Those figures, as you know, have been exceeded in actual milling results, and still higher extraction is attainable by finer grinding, but with the present cost of power and supplies is scarcely justified from a commercial point of view.

The method used in our mill—we have never called it a process—is but a combination of well-known devices and chemicals to obtain the desired end; we have no secrets, chemical or otherwise, and from the first day the plant has been open to the inspection of metallurgists and all information or data asked for by responsible parties has been frankly supplied. The stride from a $15 per ton milling cost in 1894 to a cost of $1.50 per ton in 1910 is a great one. Still, I believe the milling of low-grade sulpho-telluride ore is today in its infancy; improvements in machinery and methods will come, making toward higher efficiency, better extraction, and lower working cost. For the straight wet-milling of sulpho-telluride ores a $1.25 working cost is now in sight on a basis of treating 10,000 tons per month, while the dollar milling cost is perhaps not far distant, and could possibly be attained in a well designed plant treating not less than 15,000 tons per month. In neither estimate, however, is amortization taken into account; the figures cover only the bare milling and maintenance cost.

Stratton's Independence mill, delayed for a time through financial reasons, started in April 1909, with a nominal capacity of 4500 tons per month, enlarged in December of that year to 7000 tons, and with the addition of the complete second unit last month, reached a capacity of 9000 tons. The mill, through the energy and ability of the staff, was profitably operated from the start, and is now earning 10% per annum on the capital of the company, and has treated to date 120,000 tons of dump rock; sufficient, I believe, to take it out of the class of 'metallurgical impossibilities,' if not to establish it as one of the chief industries of the Cripple Creek district. We all, more or less, realize what the local milling of the low-grade ores means to Cripple Creek. It does not offer a large or immediate reward to the mine-owner, but on the contrary calls for a considerable expenditure of capital; hence the development of the milling of low-grade ore must proceed conservatively along the lines of consolidation of small properties or joint milling on a co-operative basis. Milling the low-grade ores in the district does, however, mean the maintaining of, and possibly an increase in, the output of shipping ore; the prolongation of the life of the camp, I might say, indefinitely; the steady employment of large numbers of men in the mines and mills and the purchase of vast quantities of supplies. In a word, high-grade production tends to make millionaires, the low grade, a populous, prosperous, and permanent community. The Cripple Creek district will, I hope, continue to give us an occasional millionaire and an ever-increasing community of active and prosperous workers.

I believe, gentlemen, you will ever find cause for congratulation in the fact that you were pioneers in this low-grade milling industry. Your work has shown that sulpho-telluride can be concentrated, that the tailing from the concentrator can be cyanided, and ores assaying less than $3 per ton can be milled at a profit; and I sincerely thank you for your co-operation and assistance in this great work, second to nothing that has ever been undertaken in the Cripple Creek district; where you blazed the way others can safely follow, successfully copy, and, let us hope, in time improve. Nevertheless, I would not have you forget that great as has been our responsibility, and arduous the work, yet I believe the ultimate credit is due to the directors of Stratton's Independence, Limited, who eight years ago, realizing that one-fifth of the production of their mine was finding its way into the ore-house dump, started research work looking toward its recovery; first, by electro-cyanide methods, later by erecting and operating an experimental plant at a cost of nearly $60,000, and experimenting in various ways for fully four years; lastly, sanctioning the expenditure of more than a quarter of a million dollars in the plant we erected and are now operating. At all times I felt I had in our board real men behind me, gentlemen who supported and encouraged me at every step and who never lost confidence in the ultimate outcome of the undertaking. To these gentlemen is due, then, the full credit for introducing low-grade milling into the Cripple Creek district, and it is through their keen business acumen that success has been achieved and that we are here tonight to celebrate it, even at a time when others continue to use their low-grade ore to ballast railways and fill waste places along the right of way. Much has been said and written of late about the great and little-understood doctrine of conservation, but here is true conservation, the creation of a great and profitable industry from the waste rock of yesterday. A new era is dawning over the Cripple Creek district, local milling is firmly established by two great mills, the largest ever erected in the district. This, however, is but the beginning of home treatment, which, I believe, will rapidly expand in the near future and very soon cover the entire field. Cyanogen is king.

A down-draft furnace was invented about 1904 by the late Horace F. Brown, inventor of the Brown mechanical reverberatory furnace. Mr. Brown's idea was to introduce the ore at the top of the furnace in comminuted condition, the intense heat causing the ore to be reduced to a molten or semi-molten state before reaching the bottom of the furnace. The principal application of this departure from the time-honored practice that the inventor had in mind was the reduction of iron ores, particularly those of the Mesabi range of Minnesota, where the ore contains a large percentage of fine. Several trials of the down-draft furnace at Pittsburg, Pa., resulted successfully, but Mr. Brown died before having fully worked out his ideas to completion. He also calculated to apply the furnace to the reduction of auriferous and argentiferous ores of the West, and had he lived would probably have made a success of his furnace.

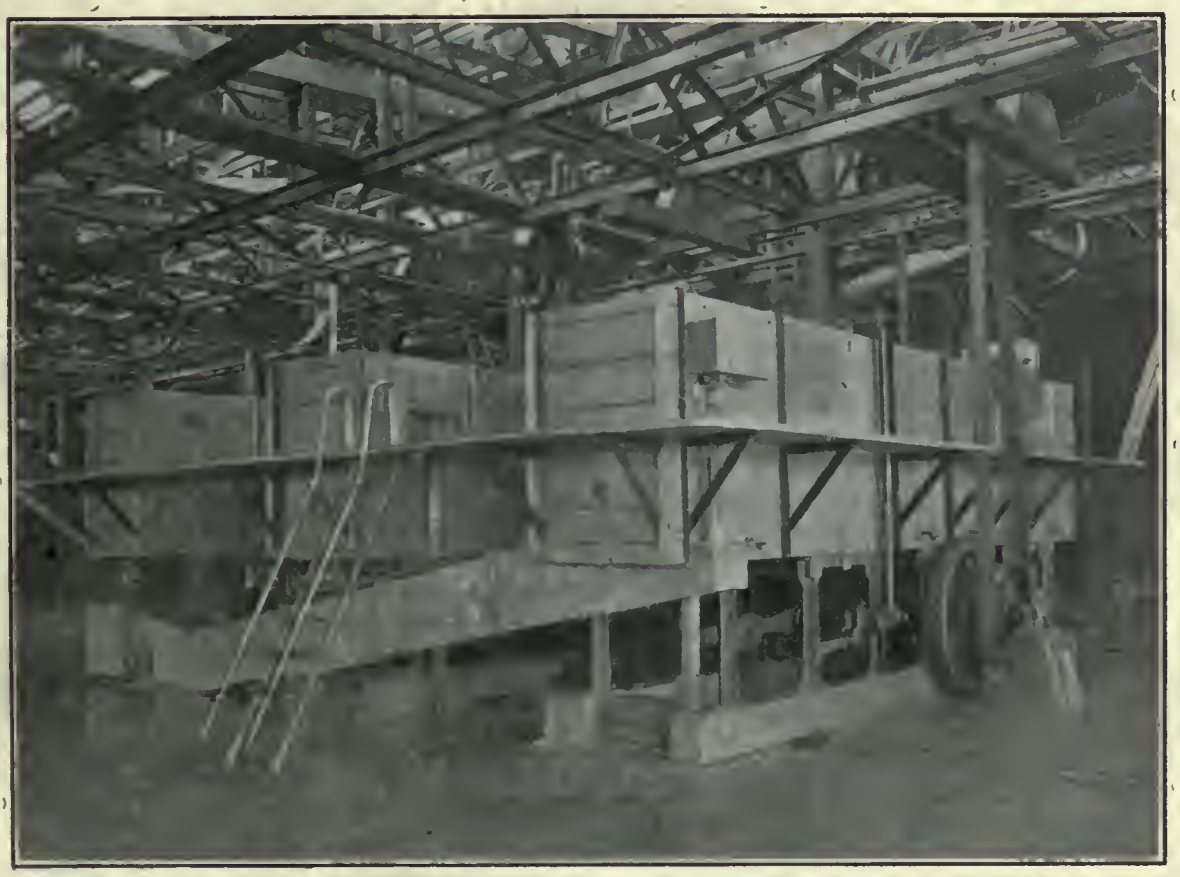
Designing a Thousand-Ton Concentrating Plant

By Charles C. Christensen

In the following pages is illustrated the method of planning a modern concentrating mill. The one described represents, in all its details, the most recent practice in fine-ore concentration, for treating a chalcopyrite ore. In designing it, the assumption has been made that electric current can be bought, transformed to the proper voltage, and distributed to the different motors in the mill. These are arranged so as to give unit drives to the several sections of the plant. The concentrator proper is planned to be divided into five sections, each of 200 tons capacity per 24 hr., with a separate crushing plant of double the capacity required, so as to run in the daytime only. In this crushing plant would be put one crusher, such as a No. 7½ Gates, set to crush to 3½ in., screening out approximately 25 tons per hour of 1-in. material. The rejected matter would be sent to two No. 5 crushers set to crush to 2 in. From the two machines it would be expected to screen out about 30 tons per hour of 1-in. material. This would leave 45 tons to be distributed among three No. 3 Gates crushers set to about 1½-in., screening out about 25 tons of 1-in. material, returning the remainder to the same machines for re-crushing. Thus in 10 hours 1000 tons of 1-in. material would be made ready for the concentrating plant. The ore as it is taken from the mine in cars should be discharged into a large steel ore-bin above the largest crushers, and the crushed ore transferred to the concentrating plant by belt-conveyors discharging by an automatic tripper, into the ore-bins, behind the crushing rolls.

The five sections of the concentrating plant are designed alike and but one will be described. The crushed ore is to be drawn from the bin by a Gates, type 'H' wall-feeder, and discharged into the first set of 36 by 10-in. crushing-rolls, which should be set approximately at ½ in. At this point, water could be added if found desirable, and the crushed material would fall with the water into the boot of a 10-in. vertical bucket-elevator, which would deliver the crushed ore into the only sizing-screen required. This trommel would make a division at, let it be assumed, ⅜ in., which size could be altered at any time by either a coarser or finer screen as found desirable. The material coarser than ⅜ in. would fall by gravity into the second set of 36 by 10-in. rolls, set at ¼ in. This crushed material would have to be re-elevated and re-screened. The material finer than ⅜ in. would pass at the end of the trommel into a 20-in. Richards annular vortex classifier, designed for use in connection with Hancock jigs. The object of this classifier is to make an unsized spigot-product ranging from the coarser size, according to the perforations of the screen, down to as fine as the jig can conveniently handle while making clean concentrate. The usual range on a ⅜-in. material is down to approximately 20-mesh, treated satisfactorily on one machine. The classifier can be regulated to a nicety, and the entire scheme of classification is founded on the water being at a constant and known head. The overflow of this classifier consists of the slime resulting from the first crushing. The type of jig selected is the Hancock, and was invented by H. R. Hancock when general manager of the Moonta mines in South Australia. Up to the time of its invention the mines in that district were not profitably treating the low-grade chalcopyrite and bornite ores. By means of the Hancock jig success was made. This jig consists of a box made of 4-in. lumber properly tied with angle-irons and rods. The box is approximately 25 ft. long by 4½ wide by 5 ft. 9 in. high. It is supported upon a cast-iron frame, the operating mechanism being beneath the body of the jig. This makes the total height of the machine nearly 10 ft. It is customary, however, to put the foundation of the jig underneath the operating-floor of the mill to bring the bottom of the box about at a level with the floor. In this box and submerged in the water, is the screen of the jig. This screen is 20 ft. long by 2 ft. 8 in. wide, and is divided into a series of pockets extending across the screen. These pockets hold a ragging or bed through which the concentrate works downward into the hutch. The screen or sieve is carried on two cast-steel cross-bars securely fastened to the screen. The cross-bars are supported by four upright arms, two on each side and outside the box. These arms or rods are connected at the bottom to rocking arm-shafts which are connected to levers the ends of which engage a three-way cam on the main drive shaft of the jig. This main drive shaft revolves at 60 to 65 r.p.m. and the result of this motion is a reciprocatory movement imparted to the sieve which can be described as an upward and forward, and downward and backward movement, so adjusted that it can be regulated to suit different kinds of ore. The number of reciprocations of the screen is 180 to 195 per minute. The Hancock jig will make clean concentrate in the first, second, and third hutches. The remainder of the jig can be devoted to making middling sufficiently rich to pay for re-grinding, and to making tailing which it would not pay to re-treat. The use of this jig simplifies the construction, decreases the size, and avoids many usual complications in laying out a concentrating-mill. The Hancock jig will do away with all trommels, except an oversize screen, and will simplify the arrangement of launders and transmission of power. All concentrate is deposited in the hutch, although it can be arranged to take off a clean concentrate from the top of the screen, if it is necessary. In operation, the fine material in the feed passes down through the screen into the hutch at once. The first screen has the finest mesh and is over the first compartment. The coarser part of the feed here forms a bed for the fine concentrate. The next hutch compartment receives the medium-sized concentrate, and the third hutch compartment the coarse concentrate. In the last part of the jig, commencing where the coarse concentrate comes down, the screen consists of plates punched ⅛ in.

larger than the largest size material the jig is handling. In this section of the jig an artificial bed made of round iron punchings, hematite, or other heavy material of a suitable size, is used. At this point the jig is a classifier as well as a concentrating machine. Each hutch is provided with an independent water supply, so that its action can be regulated as to the kind of material taken down into the hutch, and also as to the cleanness of the concentrate. This latter applies only to the coarse-concentrate compartment. The close bed over the fine-concentrate compartment prevents any sand from going down into it. In the first section of the jig the hydraulic classification action carries along the fine sand while the coarse concentrate is passing down into the hutch. This is an important feature



Hancock Jigs in the Mill of the Federal Lead Company.

of the jig. The last two hutches are usually used for middling, as practically all the free mineral content of the feed is stratified and taken down into the hutch in the first three compartments. The dimensions of the hutch compartments can be changed in order to suit different requirements by moving the cleats which hold the hutch divisions. This jig will handle 100 tons per day as well as 500, and it is therefore just as well suited to a small concentrating plant of 100 tons in 24 hr. as to a larger mill.

The middling of the jig would fall by gravity and water into a standard 6-ft. Chilean mill for regrinding. This mill may be described as a circular trough or dish in which the crushing is done. The trough carries a rolled-steel ring-die about 5½ in. thick, upon which three rollers travel. An iron 'spider' is carried upon the central vertical shaft, and upon this spider are the journal boxes for the shafts of the three massive grinding rollers. The rollers are each of a solid disc of cast iron, shod with a rolled-steel tire 4 in. thick, held in place by wedge bolts and having a heavy shaft drawn firmly into a tapered hole in its centre to form its axle. These roller-shafts have three collars of large section, integral with themselves, which prevent excessive lateral wear. The journal boxes carrying these shafts are adjustably secured to the spider by means of trunnions placed horizontally and at right angles to the wheel shafts. This provides flexibility of the rollers and renders them entirely independent of each other in passing over obstructions on the die. It also provides against excessive strain in the driving spider, which would be occasioned by uneven material upon the ring-die. Centrally situated upon the spider is the circular feed-trough, provided with three discharge-pipes, which guide the material being fed to a point upon the ring-die immediately in front of the approaching roller. Just back of each roller is a moving wing or mould-board which deflects the water, with the sand in suspension, upon the screen. The action of the rollers also materially assists in the work of screening. The inclined outside rim on the main trough or dish, is provided with six large openings to which are secured screen-frames carrying wire cloth, or perforated metal, affording a large screen area, of such a mesh as to release all mineral value without excessive sliming. Usually the screens vary from 12 or 16 to 20 mesh, depending upon the deposition of the mineral. The pulp from this Chilean mill would be elevated by a bucket-elevator, and would join the original slime

from the overflow of the annular classifier, for slime treatment. This combined slime-pulp would pass by gravity with water into a combined spitzkasten and vortex classifier. This classifier is a recent development and, being a combination of two well-known devices, provides a close sizing of the particles with the least possible hydraulic water. This classifier would be provided with three spigots, which would make three sizes, to be treated on four concentrating tables. The overflow of this classifier, consisting of the finest slime, would then be dewatered and the pulp thickened in two 8 ft. diam. by 8 ft. deep callow tanks, with siphon feeds, and this pulp would be distributed to four 6-ft. suspended vanners, equipped with corrugated belts. In practice it has been found that by dewatering fine pulp without loss, and by using corrugated belts, the tailing of vanners on the finest material is reduced to a minimum of value. Above the crushing rolls should be a 3-ton trolley running on suspended track with a 2-ton chain-block for roll repairs, and above the line of Chilean mills a 6-ton trolley and 3-ton chain-block to handle the Chilean-mill repairs. Steel buildings on stone or concrete foundations should be used to house the machinery, wherever possible.

Lead has recently risen in price $2 per cwt., or to a 4½c. basis. Lead production in 1909 was 922,206,000 lb. and in 1908, 827,736,000, both of these totals including lead smelted in bond. Daniel Guggenheim is quoted as saying that the American Smelters Securities Co. is now producing at the rate of 152,000,000 lb. per annum and A. S. & R. Co. 477,300,000, so that the total output of both concerns this year is expected to approximate 630,000,000. Production of lead by these two companies is partly from owned and controlled mines, but more largely from custom ores, bought in the open market or on time contracts, on the basis of market prices for metal contents at the time of purchase. Estimating one-quarter of the ore treated as being 'in process,' the rise in lead, if the advance be sustained, means additional profits to the two companies of between $150,000 and $160,000. Trade authorities look upon a rise of a cent a pound as unlikely, at least in the immediate future. General opinion is that supply is equal to demand.

The mine-rescue cars of the U. S. Bureau of Mines have all been outfitted and sent to their stations. The assignments are as follows:

Car No.	Headquarters.	Engineer in charge.
1	Wilkesbarre, Pa.	C. Enzian.
2	Trinidad, Colo.	J. C. Roberts.
3	Evansville, Ind.	R. Y. Williams.
4	Rock Springs, Wyo.	S. S. Smith.
5	Billings, Mont.	H. M. Wolflin.
6	Huntington, W. Va.	J. J. Rutledge.
7	Pittsburg, Pa.	J. W. Paul.

In addition stations are maintained at Pittsburg, Pa., Urbana, Ill., Knoxville, Tenn., McAlester, Okla., Seattle, Wash., and Birmingham, Alabama.

Tin mill-screens made of a good quality of Russia iron are often preferred by mill foremen, as they are inexpensive and last very well.

Nome Placer Mining

By T. M. Gibson

*The Pioneer Mining Co. has had its usual successful season. Its spring clean-up was approximately $700,000, and the summer sluicing season will add about $360,000 to this sum. The company had such rich ground in the Moonlight creek area that its workmen could not withstand the temptation to steal. Two suspects were followed to Seattle and arrested when in the act of selling gold-dust. They were made to disgorge $14,000 worth and are now being held for trial. Investigation developed the fact that several men were in the ring and about $6000 worth of gold was recovered from hiding places about Nome. The thieves were all Mr. Lindeberg's countrymen, and he is inclined to be lenient with them. Jafet Lindeberg, the president of the company, says it will declare a 14% dividend this fall, amounting to $700,000. The company now has $1,500,000 in the treasury. The splendid ditch system of the Miocene Ditch Co. was acquired last spring, after extended negotiations, together with all property held by that company. The Miocene Ditch Co. was capitalized at $1,000,000 and the Pioneer company already owned $186,000 worth of its stock. The deal taking over the balance was based on 50c. per share, or $500,000 for the whole property. The Pioneer company agrees to pay to the stockholders of the Miocene company 20% of the gross output from its operations until the full purchase price has been paid. The Pioneer company has used the water from this ditch system to excellent advantage during the past season. A hydraulic elevator on Glacier creek has been run and $80,000 mined at this point. Another hydraulic elevator was used on the McKay bench near Moonlight Springs, where $90,000 was mined, and it is estimated that $20,000 was left in the last pit because the sudden freeze October 1 prevented cleaning the bedrock. Another elevator on Bench claim No. 2 Below Specimen has $30,000 to its credit, and $140,000 was taken from open-cut work in the Moonlight area. On No. 1 Specimen, direct hydraulic operations were conducted, using a giant to stack tailing. This claim has $20,000 to its credit. The Pioneer company will not do any drift mining this winter, but will do considerable work improving the Miocene ditch. A cut-off through the Clara Creek divide will be made, and this together with a syphon line across the Clara valley will cut out about two miles of ditch in a section where the loss by leakage is heavy. The cut-off will be 1800 ft. long, 600 ft. on each end being open-cut, with 600 ft. of tunnel between. The open-cut work has already been completed. The tunnel will be 12 ft. on the bottom, 10 ft. at the top, and 5½ ft. high in the clear. Another tunnel 900 ft. long, of the same dimensions, will be driven through a rocky point near Hobson creek known as Cape Horn. The present tunnel from Glacier creek to Anvil creek, which is about 1000 ft. long, will be enlarged to the same size as the other.

*A separate account of dredging operations at Nome in 1910 will be presented in the *Mining and Scientific Press* January 7.

All this rock work will be done by hand. It is the intention of the company to enlarge the Miocene ditch to a capacity of 8000 miners inches. A steam-shovel has been working at this for the last two years. Next year four more shovels will be shipped in, and it is expected the work will be finished by the first of next October. The following season the shovels will be used on the Pioneer ditch, and its capacity will be increased to 5000 inches. Mr. Lindeberg is planning extensive ground-sluicing in the vicinity of Moonlight and Little creeks. He estimates the company's holdings in that area to contain $14,000,000. He says it has 100 acres that will yield $100,000 per acre, and another 100 acres that will yield $40,000 per acre. This area is from 20 to 45 ft. deep, and he will ground-sluice 10 to 15 ft. of the surface tundra and drain through the big open ditch leading down Little creek. He believes the warm air of the summer will soon thaw the gravel which lies underneath. He contemplates the use of mechanical elevators to handle this gravel, and expects to handle the entire area at a cost of between 30 and 40c. per cu. yd. He may be overestimating the gross yield, but this area is conceded to be very rich. He expects to keep his surface ground-sluicing at least two years ahead of his mining. Mr. Lindeberg was fortunate in his trials, last July and August, on the charges of perjury in connection with litigation over the Bear Cub mining claim, in which the Pioneer company has an interest. James Murray and Barney O'Reilly re-located the claim January 1, 1909, alleging that the annual labor required by law had not been performed for the year 1908. The Pioneer company set up the claim that the work had been performed by lessees sluicing old tailing on the Bear Cub claim, and also by a man who was specifically employed to do the work, and they brought an action against Murray and O'Reilly to regain possession. In the course of this suit Murray and O'Reilly subpoenaed Mr. Lindeberg to take his deposition. This deposition was taken before Mrs. Cordelia Noble, a notary public. Mr. Lindeberg in the same suit made an affidavit before Lawrence Kerr, a notary public, in which he made some of the same statements as were made in the deposition. Murray and O'Reilly alleged that certain of these statements were wilfully and knowingly false and therefore constituted perjury. The matter was brought to the attention of the Grand Jury and they returned indictments against Mr. Lindeberg on three counts, two in connection with the deposition, and one as to the affidavit. He alleged that George Grigsby, United States District Attorney, who was one of the attorneys for Murray and O'Reilly, had procured the indictments in order to aid him in the civil action over the Bear Cub claim, and much pressure was brought to bear on the administration to cause his removal from office before the cases came to trial. These efforts were successful, Mr. Grigsby being removed just one week before the cases were set for trial. Mr. Lindeberg went into the trial with two lawyers from San Francisco and five of the leading attorneys of Nome representing him. In the matter of the indictment under the deposition, his attorneys took the position that inasmuch as there has been no enabling act passed by Congress for the District of Alaska, a woman cannot legally administer an oath, and that false statements made before a woman notary did not constitute perjury. After several days of argument, and the reading of much law, the Court decided that their point was well taken, and dismissed the indictments. Some days later the trial on the indictment under the affidavit came up for hearing. Much to the astonishment of the District Attorney's office, the affidavit upon which the indictment was based could not be found, although it was supposed to be securely locked in the office safe. Search where they would, the paper had disappeared. A subpoena was issued for Lawrence Kerr, and it was found that he was on the high seas, having taken a boat for Seattle just before the case came on for trial. The District Attorney had him subpoenaed by telegraph to Seattle, but he refused to return. The last indictment was then dismissed on motion of Lindeberg's attorneys on the ground that no evidence had been produced tending to show the guilt of the defendant.

A matter for congratulation among all miners using steam-power in the vicinity of Nome is the fact that the Associated Oil Co. has established a branch of its business here during the past summer. It has erected for storing crude oil a steel tank 90 ft. in diameter and 30 ft. high. It will hold approximately 1,500,000 gallons. The oil-ship *Porter* in October discharged a cargo of oil into the tank, and the company is now ready to do business. It is announced that the company will reduce the price of oil to $2 per barrel, as against $3 that has been charged by the John J. Sesnon company during recent years. The reduction of the price of oil 33⅓% will undoubtedly be the means of encouraging the miners to renewed efforts.

A new find which may prove to be of considerable importance to Nome has been made this summer by T. M. Gibson and Pete Cavanaugh, operating No. 9 Dexter creek under lease from Leo Loewenherz. A body of pay-gravel has been opened on the left limit near the creek, lying more than 30 ft. below the bedrock in the creek. It appears to be an older and deeper valley than the present valley of Dexter. The bedrock in the creek is a calcareous schist, and as No. 9 was a rich claim, it has been worked from end to end and from one to five feet of bedrock taken up to recover the gold that had worked down into the crevices. The new find shows a low rim separating it from the present creek, and then it drops off abruptly to a depth of 30 ft. and no bedrock yet in sight. Several thousand dollars were extracted before the close of the sluicing season. The lessees installed a mechanical elevator consisting of a steel lattice-work ladder 52 ft. long, and a line of buckets bolted to double sprocket-chains, and revolving on sprocket-wheels at each end of the ladder. There are 85 buckets having a capacity of one-half cubic foot each, and these are delivered at the rate of 65 buckets per minute. The material is dumped into a chute from which it slides into a line of sluices. A 12-hp. Union gas engine supplies the power. The ground has been opened by a hopper-shaped pit or

glory-hole, which is continually widened and deepened. The material is loose and breaks down freely. Each man working on the slopes with a pick and shovel will break loose 40 cu. yd. in a ten-hour shift. This material slides to the bottom and is picked up by the bucket line and delivered to the sluices. When the slope becomes too flat for free delivery to the bottom, the hole is deepened five or six feet, and the ladder made to stand at a higher angle, when the walls may again be attacked from the bottom upward. So far very little water has been encountered. The work has not yet been carried far enough to determine the true character of the deposit, but it is believed to be an old channel which became filled by a slide of the soft schist along the north slope of the valley at this point, crowding the creek over to the south. There it cut a channel into the bedrock of what was formerly the south slope of the valley, thus making a low bedrock rim between its present bed and the deeper channel. The deposit shows in the pit kidneys and pockets of well-washed gravel, ranging from less than a cubic yard to forty or more yards in a pocket, the whole being embedded in reddish colored and much decomposed schist. The wall of the pit on the north side, next to the hill, now has a vertical elevation of 55 ft., and this shows three well-defined faults or slip seams along an exposed face of 150 ft. A sticky gouge has developed along these seams, showing them to have been lines of movement, and this is also proved by nonconformity of the stratification. Dexter creek was one of the bonanza finds in the early history of Nome, and it is confidently believed that if this new find covers an extensive area, it will influence the output of the district in the immediate future. Shafts are now being sunk to ascertain the extent of the deposit.

CALCULATING VALUE IN PLACER GROUND

By O. H. Packer

The casing ordinarily used with a power percussion-drill in testing placer ground is 5⅞ in. inside and 6½ in. outside and is called 6-in. casing. The outside diameter of the drive-shoe is 7½ in. The actual amount of the ground delivered to the panner depends chiefly upon two things: the nature of the ground and the method of drilling. To some extent the form and condition of the shoe affect results. For these reasons engineers have not adopted a uniform 'pipe factor.' Laying all arguments aside, the proper 'pipe factor' to use is the one that will give results in accordance with tests made by sinking a shaft by hand. In a large majority of cases, judging by past experience, it may be assumed that 100 ft. of hole with a 7½-in. shoe will represent 1 cu. yd. of ground. Upon this basis I have constructed the chart accompanying this to facilitate valuation calculations.

The method of panning and drilling deserves attention in this connection. I do not approve of the method of counting the 'colors' obtained by the panner. Neither do I approve of the method of panning a portion of the ground delivered by the pump. I always run through a rocker all the material obtained from a hole and then pan the concentrate, using mercury when the colors are small. The samples are kept in small numbered vials. The mercury is dissolved with nitric acid and the resulting gold weighed in milligrams. If the colors are large the sample is inquartated with silver and parted with nitric acid. In either case pure gold is obtained. If the fineness of the gold is not considered, gross error is likely to result. By weighing the pure gold, all chance of error is eliminated. If these precautions are taken, and the depth of hole kept at the proper point with reference to the bottom of the shoe, the use of my chart will give values concordant with results obtained by hand shaft sinking.

To obtain the value of the ground in cents per cubic yard by ordinary methods the pure gold being weighed in milligrams, a lengthy calculation is necessary. To avoid this calculation I have devised the chart referred to. In using the chart, begin with the weight of the pure gold in milligrams. Follow the horizontal line to the right to its intersection with the diagonal line representing the length of hole from which the gold was obtained. Follow down the vertical line to the bottom where the value of the ground in decimals of a dollar will be found. Following are a few examples:

Example 1. What is the value of dredging ground per cubic yard when 5.4 mg. of 20-carat gold is obtained from a 4-ft. hole?

Solution by ordinary method: 5.4 mg. $\times$ $^{20}/_{24}$ = 4.5 mg. of pure gold. $4.5 \times 0.0006646 = \$0.00299$ value of the gold, from 4 ft. of hole = $^{4}/_{100}$ cu. yd. $0.00299 \times 25 = \$0.0747$ per cubic yard.

Solution by the chart: Begin at 4.5 mg. (mg. of pure gold) in the left-hand column. Follow the horizontal line to the right to its intersection with the 4-ft. diagonal line. Drop to the bottom of the chart (at z) where the result $0.0747 per cu. yd. is found. If the weight of pure gold had been 45 mg. instead of 4.5 mg. the result is multiplied by 10, giving $0.747 per cubic yard.

Example 2. What is the value of dredging ground per cubic yard where 22 mg. of pure gold is obtained from 17 ft. of hole?

Solution: In this case the intersection is in the closely crowded lines. Take some multiple of 22, as $4 \times 22 = 88$. Follow the 88 line to intersection with the 17-ft. diagonal, and drop to the bottom, where 0.0344 will be found. Now divide by 4 and multiply by 10. The result is $0.086 per cu. yd. In many such cases the length of hole can be *divided* and the result *divided* by the same number.

Example 3. What is the value of the bedrock stratum of dredging ground 2½ ft. thick (last 2½ ft. of drill-hole) where 108 mg. of gold is obtained, 22 carats fine?

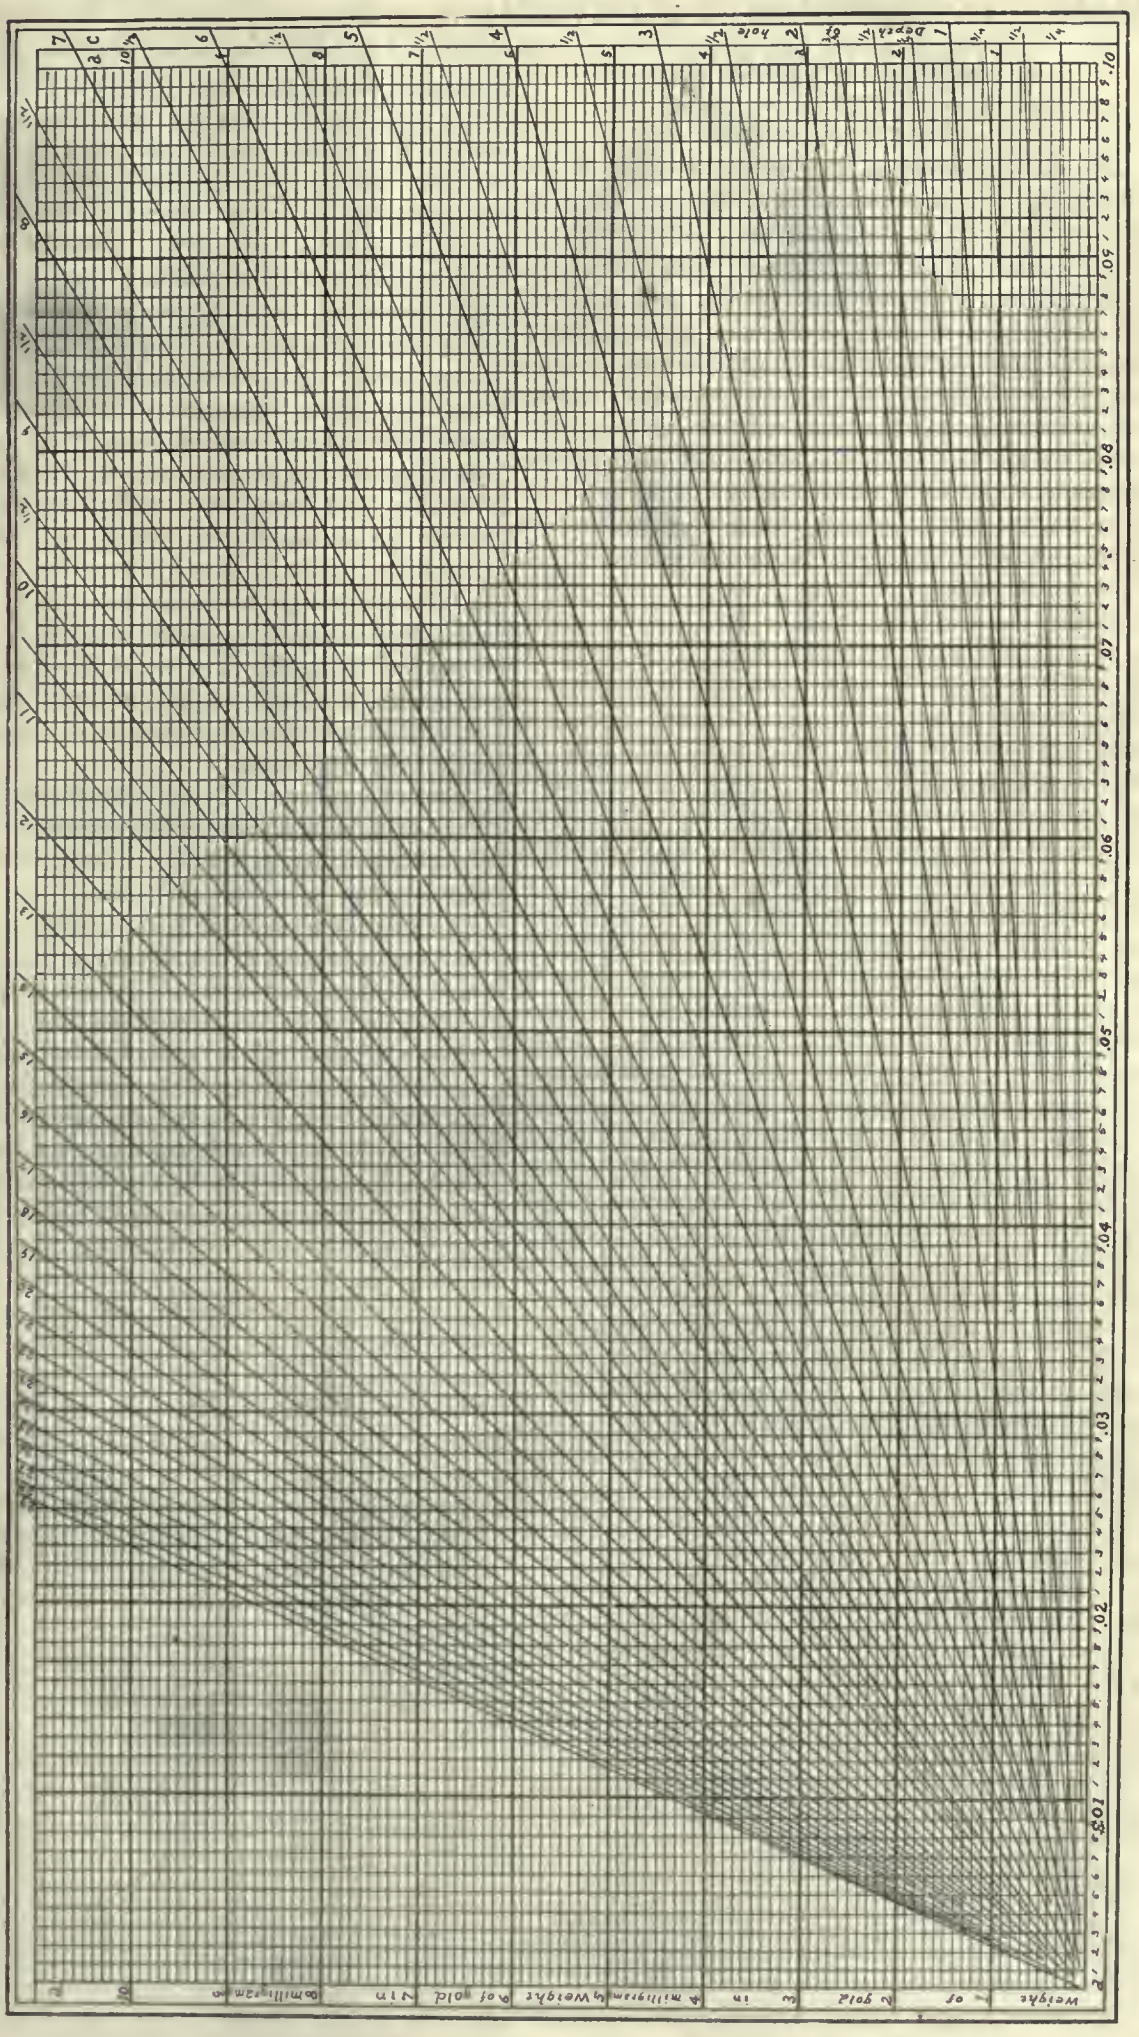
Solution: $108 \times {}^{22}/_{24} = 99$ mg. of pure gold. As the 9.9 mg. line does not cross the 2½-ft. diagonal, take $4 \times 2.5 = 10$. From the 10-ft. diagonal drop to the bottom at 0.0658, which multiplied by 10 for 99 mg. and by 4 for 2½-ft. hole, yields $2.632 per cubic yard.

If it is desired to compute values mathematically, the chart may be used to check the computations.

PROSPECTORS' CHART

For valuing placer ground after a percussion drill, 6 in. casing, 7¼ in. shoe, 100 ft. hole=1 cu. yd. 1 gm. gold=$0.0646.

By O. H. PACKER.



Metallic Sulphides in Alluvial Gold Deposits

By F. Lynwood Garrison

The main purpose of this communication is one of inquiry and suggestion. I have been for some time quite curious to know how hydraulic and gold-dredging operators manage when they have considerable quantities of auriferous iron pyrite in the black sand of the 'clean-up.' To discard this material is to incur a seemingly unjustifiable waste of gold, yet in the absence of mechanical (magnetic) concentration, or a chemical (metallurgical) treatment, such a loss is unavoidable. The gold-bearing tendency of pyrite is well recognized; it is not, however, always auriferous, even in gold-producing districts, but it is never safe to assume an absence of gold in it without definite tests by assay. The condition in which the gold is held by the pyrite need not be considered at present. It is sufficient to say it is probably both mechanically and chemically combined with the iron sulphide. Evidently that part mechanically associated will yield to amalgamation and the more readily if the sulphide is oxidized by roasting. In his paper on the 'Origin of the Gold in the Rand Banket', J. W. Gregory says, "Pyrite is so easily oxidized, and is so brittle, that its occurrence as pebbles in a placer deposit seems highly improbable."[1] George F. Becker, in discussing this phase of the subject, says: "As far as the fresh-water placers of America are concerned, there is no room to doubt the frequency of the occurrence of pyrite pebbles. For generations prospectors on the Pacific slope have recognized that rounded pebbles of pyrite afford an excellent indication of the presence of placer gold."[2] In the gold-bearing beaches of the Seward Peninsula, Alaska, pyrite is of such frequent occurrence as to occasion no comment. Indeed, instances of the presence of pyrite in alluvial gold deposits, in different parts of the world, might be multiplied many times, hence it is evident Mr. Gregory is mistaken in his conclusion as above quoted. It is not my intention at this time to enter into a discussion of the gold deposits of the Rand, but to call attention to gold in the pyrite commonly found with the black sand of many alluvial deposits. When the gravels are so rich they may be worked by hand, the proportion of gold thus contained and retained by the pyrite is relatively small, and may be neglected. When, however, the gold tenor is but a few cents per cubic yard, it would seem desirable that the gold of such pyrite add its increment to the total recovered. It is difficult to ascertain the proportion of gold lost in dredging and hydraulic operations; it must, of course, vary within wide limits; probably in most instances the recovery is not over 70 to 75% of the prospect value. It is stated that at Oroville, California, as much as 2½c. per cu. yd. of gold is sometimes lost; this evidently is too much. It is perhaps due chiefly to an extremely fine state of division of the gold particles; probably the actual loss thus sustained is seldom or never known. In the beach deposits of the southern Seward Peninsula, both iron and arsenical pyrite are common. In some places this pyrite carries gold, but at others none, or very little, is found by assaying. It is immaterial whether or not the pyrite in the gravels comes from gold veins or is due to concretions, probably both sources have contributed some proportion; in either case the iron sulphide is likely to carry gold; that in the concretions being deposited contemporaneously with the formation of the concretions. According to Skey, "one part of pyrite will precipitate more than eight parts of gold."[3] It has been repeatedly shown that nearly all natural metallic sulphides will precipitate gold from auric chloride solutions. It should be borne in mind, however, that although it is easy to obtain a gilded pyrite in laboratory experiments, it is never found in such condition in nature. Microscopic crystals of gold deposited on pyrite in alluvial deposits, under natural conditions, are not uncommon, but it never occurs as a uniform film on the sulphide, except when artificially produced.

According to J. Malcolm Maclaren, "The high tenor of gold in certain pyrite deposits in the gravels of southern Siberia, British Columbia, and elsewhere, suggests the possibility of some of the placer gold in these regions having been derived directly from the decomposition of auriferous pyrite, itself probably of secondary origin."[4] J. E. Spurr calls attention to the pyrite frequently found in the gulch gravels of the Yukon gold district, Alaska. Here it occurs sporadically disseminated in the schists, and finds its way into the gravels as the result of erosion. It is a common practice of the more economical miners in this district to separate the black sand with a magnet, then roast, grind, and pan the decomposed pyrite. In this way considerable gold is obtained."[5]

In California the question of saving the pyrite, or rather the recovery of the gold in it, does not appear ever to have been seriously considered, possibly for the reason that it is not present in sufficiently large amount to attract special attention. In Alaska they appear to have trouble enough in large operations, without bothering about the pyrite, but there are localities, such as some of the rivers in Colombia, South America, where the andesitic country-rocks carry so much of this material that the resulting gravels are full of it. In panning, of course, the pyrite washes off with the black sand, but in large operations, unless saved, it seems to be a means of serious loss of gold. It is unfortunate that there are not some reliable data relative to the gold value in such pyrite. As far as I am aware, no careful systematic tests, or sampling, with this object in view, have yet been made.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Importance of Prospecting Vein Walls

The Editor:

Sir—The following results of a mine examination may be of interest to the student as well as to the mine-owner. The importance of cross-cutting into the vein walls, or at least of putting in a drill-hole now and then, was in this case clearly demonstrated. Many a miner has run alongside his vein until some accident, such as a misjudged shot, or a cave, has revealed the unexpected treasure. This particular case described was where a small vein had been followed by an adit for several hundred feet, the foot and hanging walls being apparently without a break, but on close examination the walls showed evidences of faulting previous to the formation of the vein, for the vein itself was regular and without a break. To make sure that nothing was being overlooked, holes were drilled into the walls near the breaks referred to. The results of assays of cuttings from holes drilled into the walls, and of assays of samples taken across the material after shooting the holes, are of interest. It will be noticed that there is a wide discrepancy between the value of ore as shown by the drill-holes and of that obtained by sampling. This is only natural, for two reasons. First, the drill-hole may or may not strike a good portion of the vein, and second, less drillings come out of the hole for each consecutive inch, the starting drills having wider bits and cutting more rock than the smaller bits in the deeper portion of the hole. Where an upper and lower hole is tabulated, one is directly under the other.

Position of hole. Feet.		Depth drilled. Inches.	Gold per ton.	Hand samples of vein. Width of ore. Inches.	Gold per ton.
20	Upper	24	$27.04	24	$64.10
	Lower	27	19.24		
25	Upper	18	21.73	24	93.00
	Lower	24	21.73		
30	Upper	18	33.35	24	10.33
	Lower	26	10.33		
35	Upper	20	2.06	24	43.40
	Lower	12	51.67		
40	Upper	12	2.06	24	18.60
	Lower	24	31.00		
45	Upper	24	20.67	24	19.12
	Lower	30	20.67		
95	Centre	18	47.54	18	22.73
100	Upper	18	4.63	18	20.67
	Lower	14	15.45		
105	Upper	18	1.03	18	37.25
	Lower	18	17.50		
110	Upper	18	30.47	24	43.90
	Lower	3	5.00		
115	Upper	18	1.03	24	1.03
	Lower	18	0.50		

The vein which had been followed by the adit averaged about 12 inches in width and assayed from a trace of gold to $15 per ton, but at the places where the walls assayed the highest the vein proper was found to be lowest. On shooting out at 115 ft. the 'wall' vein was seen to take a sharp turn which accounts for the assays being so poor. On a lower level of this mine a hole was drilled into the wall near a break and each foot of drillings kept separate with this result: At 130 feet, first foot, $3.10; second foot, $10.33; third foot, $37.65. Here again is an indication of an orebody in the walls close to the vein previously followed and where the walls were of better grade than the defined vein. Sufficient has been shown to demonstrate the importance of carefully examining the walls of a vein, no matter how regular they may be, and particularly at or near places where the walls have the appearance of having been broken by a slip or fault.

Tin Smelting

The Editor:

Sir—The note in the *Mining and Scientific Press* of November 12, appears in error, unless the practice of tin smelting has been radically changed since my period of activity in the business—a matter of thirty years. I believe Mr. Carter has confused the manufacture of tin plate with tin refining. The latter, a simple matter of liquation and boiling or 'tossing,' is invariably performed at the smelter, and three trade products, 'common,' 'refined,' and 'grain' tin separated if required.. The output of Cornwall is, I believe, yet smelted, with or without, foreign tin ore at the local smelters, and the refined metal shipped to the best market. South Wales is the seat of the British tin-plate industry and much of the Cornish tin finds its way there, not for refining purposes, but to coat steel plate in the manufacture of the tin plate of commerce. The tin plate works are situated in South Wales because the steel mills and coal mines are there. Tin forms less than 3% of the weight of the finished tin plate. The finest tin-plate works in the world are in the United States. The term 'block tin' derives its origin from having been cast in blocks of 448 lb. The term is much used in Cornwall to distinguish between tin ore called 'black tin', and metallic tin called 'block tin.'

Denver, November 18. PHILIP ARGALL.

The Editor:

Sir—I notice in your issue of November 12 an inquiry by G. H. Carter relating to the smelting, refining, and use of tin in Great Britain. The metallurgy of tin is kept more secret than any other branch of the art. The Cornish smelters never divulge anything, any more than do the Straits Trading Co. at Penang. The works are strictly private and none of the scientists are allowed to breathe a word. The German smelters sometimes write something about their practice in mixing various ores, but do not impart much information. The Cornish smelters produce a completely refined article, and the Swansea tinplate manufacturers do not do any

refining. The smelting is done in Cornwall because the ore is on the spot and it is easy to bring the fuel from the South Wales coalfields. Foreign ore and concentrate is brought to Cornwall especially from Bolivia and South Africa, but most of this imported material nowadays goes to the works near Liverpool, where both Strauss and Williams-Harvey have erected smelters. Fuel is just as convenient there as in Cornwall and shipments are easier arranged. In addition, much of the tin there produced is used in the Lancashire and Midlands alloy trades, so that the market is nearer than in Cornwall. It is quite a usual mistake in America to suppose that tin is smelted in South Wales. Nothing is done there, and the trade is confined to tinplate manufacture. It would be a most uneconomical procedure to make tinplates in Cornwall, for the steel sheets are made in South Wales, and would, together with the fuel, have to be sent to Cornwall. Besides, South Wales is nearer the home markets for plates and nearer the shipping ports for the export trade. While writing of tin smelting in Cornwall, I may say that much dissatisfaction is continually being expressed by the Cornish miners at the present method of selling tin concentrate by public tender at the fortnightly ticketings at Redruth. The prices obtained are lower than those offered in private contract by German smelters. As a matter of fact small amounts are sold to German firms, but it has to be done surreptitiously. If a regular producer dropped out of the tin ticketings, the heavens would fall or something equally in the nature of a cataclysm would happen.

London, November 23.

Laboratory Agitation Apparatus

The Editor:

Sir—In the *Mining and Scientific Press* of September 24, 1910, George A. James gave a method of air agitation for laboratory experiments, from which method I evolved the following scheme.

Instead of a flask turned upside down, a Squibb's separatory funnel is used. The ore and solution having been introduced into the funnel, close the funnel with the glass stopper, and mix thoroughly by shaking. The funnel is now placed in a stand, and the glass stopper replaced by a one-hole rubber stopper, which is connected by a glass tube and heavy wall rubber tubing with a filtering pump. The pump is started, thereby creating an incomplete vacuum on top of the solution in the funnel. Slightly opening the lower stopcock has now the effect of drawing the atmospheric air through the pulp and solution, resulting in efficient agitation. More than one test can be made at the same time by connecting the lower stem of the first funnel with the top of the second one, and so on, admitting air to the stopcock of the last funnel. In case of light slime, where only slight agitation is required, ordinary flasks may be used with two-hole rubber stoppers. The air is admitted through a glass tube (through the stopper), nearly reaching the bottom of the flask and is pulled away through a tube (in the other hole in stopper), which goes only a short distance in the flask and does not reach the top of the solution. The contents of several flasks can be agitated simultaneously by connecting the tube for admitting air into the first bottle, to the tube removing air from the second one, and so on.

Avino Mines Company

The Editor:

Sir—In your edition of November 26 I notice a letter from J. Parke Channing, in answer to my communication of October 21, in which he states that he believes the presence of tetrahedrite in Avino ores caused the trouble in concentration—"this being the main carrier of the silver." The two tailing dumps at the mines—resulting from water concentration and lixiviation, respectively—are still in evidence against the conclusions drawn by Mr. Channing. It is quite apparent from his letter that he is not personally familiar with the property or the character of these dumps. He states that the concentration, aside from loss in silver, was good, and further states that lixiviation was carried on very successfully. The two tailing heaps have both been thoroughly sampled, and the results show that the silver contents of the lixiviation tailing are higher than the tailing from water concentration, while of the "other metals" for which he claims a good extraction, copper and lead are higher in the tailing from water concentration than in that from lixiviation, so that his point is not well taken. Mr. Channing's informant could not have been familiar with the contents of these two tailing heaps. The results of milling and sampling tailing do not indicate the enrichment of the ore in silver by the presence of tetrahedrite.

If the concentration of the ores was successful, except for losses in silver and lixiviation, why did the property come to grief and require re-organization three different times in order to raise funds to continue operations? It is only a short time ago that two experts examined the property and recommended erecting a concentrating plant to re-handle the concentration tailing, seeing in it a sufficient asset to warrant further prospecting of the mine and further testing of the ore by water concentration. All this was to be accomplished from the revenue derived from the concentration of the existing tailing, the principal return being expected from the copper content.

Filter-Pressing Slime

The Editor:

Sir—With reference to the article by M. W. von Bernewitz on 'Filter-Pressing Slime', which appeared in your issue of September 17, the filter-press mentioned in the last paragraph as having been used by Alfred James was invented by me while in Kalgoorlie in 1905, and patents secured in New Zealand, Australia, South Africa, Mexico, United States, and Canada.

J. CHISHOLM.

Pavda, Voviya, Perm, Russia, October 14.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

It is poor business to build a mill on a prospect or even a mine having extensive development before there is enough ore in sight to at least pay for the mill. This axiomatic proposition is too often lost sight of, or ignored.

Faults frequently intercept the continuity of veins. If your vein has faulted and you cannot find it, employ a geologist. He may lack mining experience, but he possesses valuable geological knowledge, and in that you may be deficient.

Oil-land withdrawals now outstanding, including some private lands within the exterior limits, aggregate 4½ million acres, and are comprised within the States and Territories of Arizona, California, Colorado, Louisiana, New Mexico, Oregon, Idaho, and Wyoming.

A fractional claim is not infrequently found by some wide-awake fellow in the heart of an old mining district. Have a good careful look at the mine map of the district. Fractional claims, however, are often of such shape that no extralateral right can be secured.

New milling machinery installations should be carefully considered. Be sure the machinery you have in mind is suited to your ore. A little investigation along this line may save you thousands of dollars, and may mean the difference between success and failure.

Gold frequently occurs in quartzite, and when such is the case is usually found to be accompanied by intrusive rocks. There are exceptions to this, however, a noted instance being the Gold Mountain mine in the Blackhawk Mountains in San Bernardino county, California.

Close concentration of copper ores is one of the most difficult problems of the metallurgist. The refinements of concentration may easily be carried far beyond the limit of economic success. Millmen seldom aim to make an ultimate saving exceeding the cost of profitable operation, although such saving may easily be within the range of mechanical possibility.

Extensive surface mineralization is a feature of nearly all great mines. The valuable ore may be lacking on the surface, but evidences of a vein fissure, the rocks bleached or deeply stained with iron or other oxides, softened by oxidation and crushed by pressure and movement, are the principal phenomena that are evident on the surface of a great mine. To these conditions there are exceptions, but not many.

Large beds of fragmental material in gulches or depressions cemented by iron oxide, suggest to the average geologist the presence of iron-bearing springs in the vicinity, and in not a few such instances it has been found on examination that the springs issued from a lode or vein of pyritous ore, often containing copper—not rich, perhaps, but certainly justifying prospecting, particularly below water-level.

Surveys of the public lands were long made by contract, but Congress at the last session increased the appropriations over former years and authorized the abandonment of the old method of making surveys. The reports thus far received from the surveying forces of the Department of the Interior indicate that the surveys are being made under the new system at a reduced cost per acre, and at a very great increase of speed. Surveys that have had heretofore to wait years for examination will now be adjusted and approved, on receipt of data from Government surveyors, without delay.

Malachite, the green copper carbonate, is not the only green mineral. There are other green ores containing copper, and several ores and minerals of green color that contain no copper. Among these latter are the green micaceous magnesian mineral, mariposite; omphacite, a green pyroxene; variscite, a hydrous aluminous phosphate which has a deep emerald-green color; glauconite, an iron silicate, occurs abundantly in some sandstones, and as incrustations and filling cavities in eruptive rocks; vivianite, a hydrous ferrous phosphate, though generally blue, is sometimes green, and is often mistaken for azurite or malachite.

The silicious gold ores, as they are called, of the Black Hills occur in Cambrian formation and are either mineralized quartzite, or silicified lime shale lying upon the quartzite. The ore contains a small amount of tellurium associated with the gold. Few of these ores, either oxidized or unaltered, prospect in free gold. The value can only be ascertained by assay. The ores have been treated by smelting, by barrel-chlorination, and by cyaniding, the latter being the most commonly practised. The unoxidized ores have as yet not been treated with marked success, and the solution of this metallurgical problem offers a substantial reward to the one who can overcome the difficulties.

The cost per ton of operating any kind of a mine must be determined wholly by the conditions under which the mine is operated. Size and character of the vein, hardness of the ore, cost of labor, amount of water and waste to be handled, magnitude of operations, and the expense of metallurgical treatment, all have to be considered, as well as the situation, transportation facilities, and other details. Tabulated statements of cost can only give the searcher after information an idea, at best, of what the cost in an untried place will be. It may be approximated by estimate, but trial is the only way to arrive at it arbitrarily, as is shown by the lowering of costs at certain mines by change in method or to some other circumstance.

Special Correspondence

JOHANNESBURG, TRANSVAAL

Knights Deep, and Simmer & Jack East.—Review of the Year's Operations.—The New Rietfontein.

The annual meetings of two subsidiaries controlled by the Consolidated Gold Fields of South Africa have been held at Johannesburg during the past few days. The two companies referred to are the Knights Deep and the Simmer & Jack East, two of the most important deep-level properties in the Germiston mining area. The fiscal year of these companies terminated on July 31. During the period under review the Knights Deep earned a profit of over £300,000, while the balance to appropriation was £325,810. The company paid out 30% in dividends, the amount absorbed in payment being £193,057. Taken altogether, the results of the year's operations may be considered quite satisfactory, and an increase in dividend payments was predicted by the chairman. At the end of the fiscal year, the ore fully developed in the property amounted to 1,700,000 tons, in addition to which there are large ore-bearing areas which are not included in the above, but which are opened up for mining. The interesting statement is made that only a limited amount of work remains to be done to complete the development of the mine. The ore reserves of the Knights Deep Co. are valued at 5.5 dwt. per ton, the recovery secured during the 12 months having been only a little over 21s. per ton. In the previous year the yield was 23s. 11d. The reduced value per ton has been largely counterbalanced by a reduction in the working costs from 14s. 5.3d. to 12s. 3.1d. per ton, and this in conjunction with the larger tonnage milled has resulted in an increase of £4000 in the actual profit earned. The reports of the Knights Deep Co. should convince the most skeptical that with good management, areas of less than even 5 dwt. value per ton can be turned to profitable account in Rand deep levels. Much less satisfactory have been the results secured by the other subsidiary, the Simmer & Jack East. During the twelve months ended July 31 last, this company made a profit of £64,148, or, including sundry revenue, £71,920, as compared with £82,986 in the previous year. Difficulties have attended the working of the property during the period under review, chief among which have been a continuous shortage of native labor and the unsatisfactory developments in the bottom workings from the Hammond & Western shaft. The area opened by the Eastern & Lohse shaft, too, has not been productive. At the end of the financial year the ore reserves were estimated at 950,00 tons of an average assay-value of 5.4 dwt. per ton, as compared with under 750,000 tons of an average assay-value of 5.8 dwt. per ton, at the end of the previous year. The increase in the ore reserves is largely due to the inclusion of areas of low-grade rock which were not considered in previous estimates. The recovery secured during the year under review was 21s. 5d. per ton, as compared with 22s. 4d. in the previous year. A reduction in working expenses from 18s. 5d. to 17s. 10½d. was effected at the same time. The Simmer East is unquestionably one of the most difficult properties on the Rand at the present day. The position with regard to the ore reserves occasions anxiety to the management, and the margin of profit is by no means satisfactory when one takes into consideration the large amount of capital invested. The company has 200 stamps and 3 tube-mills, but on account of the shortage of labor and the state of development, it has been deemed inadvisable to operate more than 130 stamps, and the remaining 70 have therefore been leased to the adjacent mine, the Knights Deep. Strenuous efforts are being made to better the conditions underground and all efforts are being directed to exploring the lower portions of the mine.——The affairs of the New Rietfontein Estate Gold Mines, Ltd., a company working the du Preez Reef series to the north of Germiston, have given much cause for anxiety to the shareholders of the company for several months past. Of late the grade of the ore has been falling steadily, and as the mine is one in which conditions do not lend themselves to cheap working, the management has been quite unable to counteract the decline in value per ton by a lower rate of operation. The profit earned by the New Rietfontein company during the quarter ended September 30, 1910, was only £989. During this period a further decline in grade adversely affected the returns. It has now been decided to make special efforts to reduce the stoping widths on the reefs, and with this end in view all stoping by rock-drills has been suspended. It is trusted that this will result in an improvement in grade, although it will have the effect of reducing the quantity of ore milled.

TORONTO, CANADA

Railroad to Porcupine.— Interest in the New Camp. — Mining Affairs at Cobalt,—Mineral Production of Ontario. — Test Case Decided.

Porcupine is more in the ascendant than ever since the Ontario Government, on November 30, announced its intention of building into the camp a branch of the Temiskaming & Northern Ontario railway from the main line near Kelso. The proposed line will be about 30 miles long, and it is proposed ultimately to continue it five miles farther to the Metagami river. J. L. Englehart, of the T. & N. O. Railway Commission, expects to have the line in operation to Porcupine by July 1, as there are no serious engineering difficulties. A little trouble has arisen over a charter granted some time since to local interests empowering them to build a line to Porcupine connecting with the main line near Matheson. This charter is now declared forfeited, owing to the failure of the holders to undertake the work within the specified time limit. Their interests were acquired by E. A. Wallberg, who commenced work, and has now a force engaged on it. Legally he has no claim, but no doubt some adjustment will be made. As the result of the Government's action, a large number of Porcupine properties are changing hands at high figures. A revival of wild-catting is feared, and the Government is endeavoring to meet the situation by stringent legislation. Frank Cochrane, Minister of Mines, goes to Porcupine next week to inspect the camp, and on his return the question will be seriously considered; meanwhile the existing protective laws will be strictly enforced. It may be doubted whether the astute promoter will be successful in duping investors, as they have been bitten so often that they are becoming cautious. Shares in those Porcupine companies which have already thrown out the bait of cheap stocks are selling slowly, and it may not be easy for even those having sound and reputable enterprises to obtain money. The winter roads into Porcupine are in good condition, and machinery, supplies, and construction material are being hauled in rapidly. Among the sales of Porcupine properties reported are the three Walsh claims under option to Montreal and New Brunswick capitalists at $50,000; the Maiden-Macdonald group, for a price stated to be $250,000; the Josey group Deloro, for $150,000; and the two Knapp claims for $36,000. The holdings of the Timmins brothers and their associates, by purchase or under option, amount to 50 claims. A deal has been put through by which the Gode-Burns claims pass to Toronto purchasers at a figure close to $100,000. H. Van Cutsern, a London financier, is now looking over the field with a view to investing.

There is little news from Cobalt lately, and the market is again sagging, due partly to attention being centred on Porcupine, and partly to the approach of the holiday season. The most noteworthy incident has been the declaration of the McKinley-Darragh company of the regular 3% quarterly dividend, accompanied by a 12% bonus. Reports from the La Rose are favorable as regards the recent finds on the main property, and the Lawson, which is improving as development proceeds; but notwithstanding the excellent physical and financial condition of the mine, the prospect of a speedy return to the former rate of dividend is a vanishing one, as the management appears determined to continue a conservative policy. The Temiskaming company is mining at 500-ft. level and making preparations to sink. The Black mines have a vein of cobalt at 270 ft. in the winze which

is being put down to the 300-ft. level, and this is the best showing yet made. The Hargrave has another vein of high-grade ore 700 ft. north of the No. 3 shaft, and close to the Kerr Lake line, but curving back into the Hargrave territory. The shareholders of the Rochester have authorized the directors to raise $25,000 to continue development work.

A statement of the output of metalliferous mines and works for the first nine months of the year, issued by the Ontario Bureau of Mines, gives the silver production as 19,971,033 oz., valued at $9,792,669. The total shipments aggregated 23,824 tons, of which 19,191 tons was of ore, and 4633 concentrate. Nearly all came from Cobalt proper. Gowganda contributed 402 tons, Elk Lake 17 tons, South Lorrain 9 tons, and the production of the Lake Superior district was small. The production of metallic silver in Cobalt district was 19,468,887 oz.; and for the corresponding months of 1909 it was 18,751,549 oz., valued at $9,385,600. Considering what was predicted would result from the use of electric power, and the increase of concentrating machinery, this small increase in the output must be regarded as disappointing. The gold production shows an increase, owing to the output of Porcupine, the value for the nine months being $28,729, as against $18,926 in the corresponding period last year. Nickel and copper show increases of 56 and 28% respectively, and pig iron was this year produced to the extent of 319,698 tons, valued at $5,039,626, as against 294,698 tons of the value of $4,095,735 last year. ——Chancellor Sir John Boyd has given a noteworthy decision in a test case brought to decide whether the owner of the surface rights in land, in the deed of which the minerals and oil have been reserved, owns any natural gas which may be discovered. A number of farms in Kent and Elgin counties, Ontario, are held under such titles, the minerals and oil having been reserved by the original owners. The discovery of oil and natural gas and the operations of the companies which purchased the mineral rights, caused the farmers much loss and annoyance, and application was made to the Government for relief. The latter agreed to bear the expenses of a test case to decide the legal rights of the companies, and the court held that the reservation was valid so far as minerals and oil are concerned, but that natural gas was not a mineral, and consequently belonged to the owner of the surface rights. The companies therefore have to account to the landowners for all profits realized from gas.

FAIRBANKS, ALASKA

New Stamp-Mill at Chena. — Progress of Development on Quartz Claims on the Tanana.

Many of the people of Fairbanks and vicinity went to Chena on November 1 to see the new stamp-mill formally started. Mining men of this part of the country see in the operation of this mill the beginning of the era of quartz mining and the recovery of the gold by milling methods. While quartz development has only commenced, there are many good prospects, and the building of this mill offers a ready market for custom ore. The present outlook is much brighter, although there will be practically no stoping ground opened up till the end of November. By the first of the year Griffin, Harris, and associates, who erected this mill, probably will have sufficient ore to keep the plant operating. Some of the larger properties, any one of which would be able to supply enough ore to keep a mill of this capacity in operation, probably will order mills next summer.——The Frederick property is now being developed by Ernest Peterson, having a lease on the upper shaft, and Glazier, Crockett & Poulson, working the lower. The lower shaft has a depth of over 90 ft. and the first level from it will soon be started. The upper shaft is down over 50 ft. At 90 ft. a rich shoot of ore has been opened.——The Spaulding-Clough and extensions, at the head of Dome creek, are being developed by Huddleston Bros. as lessees, who have buildings and machinery in place; the shaft is down 60 ft., in which there is a showing of shipping ore. Stoping may begin here by the first of the year.——The group of claims on Fairbanks creek, owned by Cook Bros., Lundblad, Hopkins, and Drury, will ship some ore to the Chena mill during the winter. A 5 by 9-ft. shaft is being sunk on the Governor vein. Besides developing the known ore-shoots, prospecting will be continued. Close to these properties August Hess uncovered another rich vein, samples of the ore containing free gold. ——The left limit of Fairbanks creek, from the summit, where Lawson, McCarty, Zimmerman, and Kellum are situated, down to 8 Above Discovery, seems to be one of the most highly mineralized belts in the district.——Sherrard & Scrafford have recently leased the Newsboy and Lucky Lad claims from Herschberger, Buell & Co. These claims lie in the saddle between the heads of Cleary and Eldorado creeks. The shaft is down 40 ft. on a 2½-ft. vein, samples taken from which assay as high as $150 gold per ton.——The local test mill at Fairbanks has just finished running a 12-ton lot of ore from the Tolovana properties on Willow creek, and 9 lb. of amalgam was cleaned up, the

Chena Custom Mill.

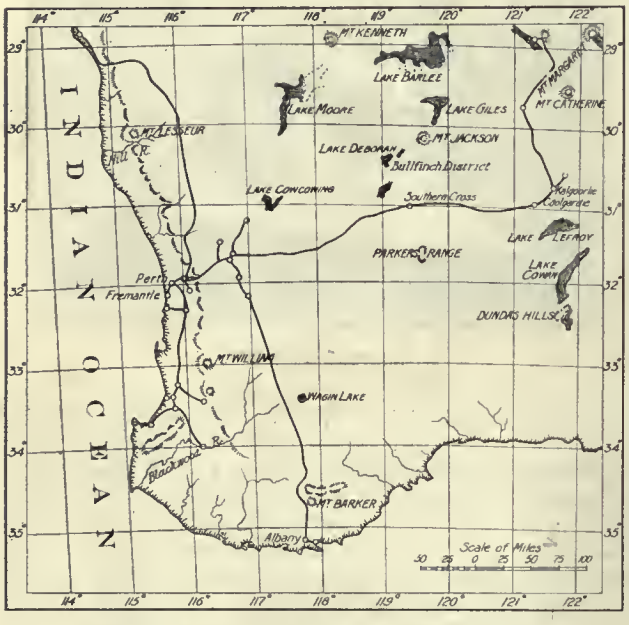
bar being valued at over $1100. Another 2-ft. vein has been found on this property, the ore from it assaying well. On this property some stoping ground has been opened.—— A shipment of ore from the Thomas lease, on the Wild Rose claim, is awaiting treatment at the local mill.—— Prospecting above an open-cut at the head of Fox gulch, that has yielded coarse gold, has led Freeman and partner to a 4-ft. vein, assays of the croppings showing as high as $20 per ton. Further work is being done to determine the extent of the find.——What seems to be a strong vein on Gilmore creek is being prospected by Laite and partners. Eight claims have been staked and the vein is exposed by four holes on each claim. At no place is the vein less than 6 ft. wide, the ore running up to $12.——Joe Cook and partner have struck two veins on First Chance creek, a tributary of Goldstream. Besides the strong evidence of scheelite, for which the ground was originally prospected, a good trace of gold was followed to a 2-ft. vein of quartz. The bottom of the shaft is just beginning to show good ore.

KALGOORLIE, WESTERN AUSTRALIA

Rich Ore in Bullfinch and a Rush to a New District. — Investigations of Pulmonary Diseases in the Goldfields.—The Associated Company.

Probably the most discussed mine in this State, and perhaps in Australia, at present, is the Bullfinch, and one of the most envied of mining men is its owner, D. Doolette, late manager of the St. George mine of the Great Boulder No. 1, in the Murchison. It came about this way: Mr. Doolette has had a prospector named Jones out in different parts of the goldfields, who some months ago pegged out a lease of 160 acres, named as above, about 25 miles north of Southern Cross, in the Yilgarn field. Work was carried on until two months ago, when results were published, backed up by three fine crushings. A lode some 1000 ft. in length has been disclosed containing a series of veins of iron gossan, and quartz in greenstone, that are wonderfully rich in gold. The ore occurs where there is a fault in the country. The iron and quartz outcrops are quite numerous, and if no gold is visible on the surface, they are looked upon as valueless. It appears that, at the Bullfinch, panning does not show the full value, assays giving

much more than is expected after seeing the pan samples. Not much notice was taken of the find at first, but when the first crushing of 60 tons returned $7500, a second about the same, and the third of 200 tons yielded $33,000—a total of $48,000 from 324 tons—a rush for the district set in, the like of which has not been witnessed since the discovery of the Coolgardie in 1902, and Kalgoorlie in 1903. Crowds of prospectors, miners, teamsters with their wagons, mining engineers, geologists, and speculators are flocking to the field. Syndicates have been formed, and companies floated locally and in the Eastern States to hold, develop, and speculate on the 2000 acres already pegged for miles north and south of the original claim. In two cases gold has been found, but shares in syndicates have risen to enormous and absurdly high prices—$50 to $3500 each—simply on the strength of an option on a base nearby. Almost every lease has been given the name of some bird, such as Bullfinch, Bluefinch, Chaffinch, Crossfinch, Goldfinch, Greenfinch, Bullfinch Extended, Deeps, Junction, and South, Bronzewing, Golden Eagle, Eaglehawk, Cocksparrow, Bull Ant, and the like. It is said that even greenstone outcrops have been pegged, and the place is booming for all it is worth. Owners of leases are simply sitting down waiting for buyers, and little legitimate work is going on. The country is heavily timbered with gum, and water is scarce and has to be carted 25 miles, costing 8 cents per gallon delivered. This will soon be remedied, if the leases prove profitable to work, by laying a pipe from the water scheme main. A township is being surveyed, and no doubt sites will command a high price. Last week's report from the Bullfinch shows 10 ft. of ore averaging $350 per ton in the north drift, 100-ft. level of No. 1 shaft; 10 ft. of ore worth $465 per ton at the 50-ft. level, No. 2 shaft, south drift; while in a water shaft the crosscut west to the hanging wall shows the lode to be 20 ft. wide and the ore worth $30 per ton. In No. 2 shaft specimen ore worth from $400 to $8000 per ton has been bagged for treatment at Kalgoorlie. The Southern Cross field has been gradually coming to the fore during the past year, as such mines as the Marvel Lock, Mountain Queen, Transvaal, Corinthian leases have drawn attention to the centre. What is liked about the Bullfinch, is that it is in greenstone country, and in Western Australia the best mines are in this rock; notably the mines at Kalgoorlie. As regards the treatment of the Bullfinch ore, it may be said that the gold is fine and little of it free. One lot of 200 tons was treated at the Associated Northern mill and averaged $160 per ton. The ironstone, which carries 60% FeO, is the only mineral that might give trouble.



Western Australia, Showing Bullfinch District.

From time to time in these notes, mention has been made of the Commission that was taking evidence on miners' pulmonary diseases in the different goldfields. The report is now at hand, and it is of great value and interest to all. Dr. Cumpston, the commissioner, suggests discarding the term 'phthisis', as it really means tuberculosis of the lungs in the ordinary sense, not including the changes that occur in the lungs due to dust; and using the term 'fibrosis' as being the more precise. This includes only the changes produced by dust, and does not refer to the changes produced by the tubercle bacillus. Of the 2050 men examined, 1805 were actually at work, and were examined under conditions as nearly as possible identical with the actual conditions under which they carried on their work. These revealed the following facts: (a) Early fibrosis was present among machine miners to the proportion of 33.16%; among non-machine miners to 7.23%; trammers, to 3.1%; and dry treatment mill hands to 24.5%. (b) Intermediate fibrosis was found among machine miners and non-machine miners; late fibrosis was found only among machine miners. (c) Pleurisy was found to be present in men engaged in different classes of mining. (d) Tuberculosis of the lungs was present in a total of 28 cases, that is, 1.5%. (e) Early fibrosis was most commonly present among machine miners and dry treatment mill men, and among those to an important extent. (f) Early fibrosis seems to make its appearance most frequently about the second year of machine work. Tuberculosis of the lungs is not yet present among miners in Western Australia to any alarming extent. The evidence seems to point fairly definitely to the infectious nature of tuberculosis of the lungs; and seems to indicate that the disease must be regarded in the light of infectious rather than an industrial disorder. Therefore, it appears certain that the action of dust does predispose to the action of tubercle bacillus. Briefly, the effects created by the presence, within the lung, of dust, are inflammatory changes throughout the lung substance, resulting in fibrosis, and the ultimate effects are: (1) diminished area of lung tissue available for the purification of the blood; (2) diminution in the amount of air which can reach the lungs; (3) diminution in the amount of blood which can reach the lungs. In conclusion, it is pointed out that, from experiments made and pathological evidence, it seems clear that dust, and dust alone, is responsible for fibrosis. No mention was made in the report of the effect of the coarse dust from the machines underground, and the fine dust in the dry-crushing plants. The matter rests there, and it remains to be seen what steps will be taken to minimize the trouble generally.

The Associated company is erecting two more Edwards duplex furnaces of 100-ton capacity each, making four in all. A No. 7½ Gates breaker, and exhaust turbo-generator are being installed. The exhaust turbo-generator of 1000 kw. is now working on the Horseshoe.

Returns for the month were as follows:

MEXICO

Activity in Pachuca District.— The Naica Lead Mines. — Palmilla and Veta Colorado.—Interest in Guanacevi.—Railroad Projects.

The recent disturbances in Mexico have been unfortunate for the business interests of the country. However, the reports of the outbreaks have been greatly exaggerated, and as long as the Mexican army remains loyal to the established government, there need be little fear of serious trouble.——The coming year will see a material increase in production in the Pachuca district, of Hidalgo. The Real del Monte y Pachuca Co., controlled by the United States S. R. & M. Co., has increased the capacity of its Loreto reduction plant from 400 to 700 tons daily, and is increasing that of its Guerrero mill from 350 to 650 tons. The Santa Gertrudis, now a Camp Bird property, will have its new 600-ton plant in operation by March. La Blanca y Anexas will soon start the machinery of its new 300-ton concentrating plant. Additions have been made to the equipment of the San Rafael plant, and there is promise of an increased output the coming year. The Mexican Light & Power Co., now in control of the Pachuca power situation, has organized, as a subsidiary, the Pachuca Light & Power Co., with a capital of $4,000,000 and a bond issue of $12,000,000. Bonds of the par value of $8,000,000 are being offered in England. It is planned to

Pamilla Cyanide Plant, Parral District, Chihuahua.

transmit power to the Zimapan district, where it is believed greater mining activity will follow the introduction of cheaper power.——As the result of having made a favorable contract with the Torreon smelter for a term of years, the plans of the Compañia Minera de Naica for the erection of a 600-ton smelter at Concho station, on the Mexican Central in Chihuahua, have been abandoned. The company is now producing from 200 to 300 tons of lead ore daily. A railroad from the mines to Concho is operated by the company, the distance from Concho to Torreon being 347 kilometres.——The foundations of the 300-ton plant of the San Francisco del Oro Co., near Santa Barbara, have been laid, and construction work has commenced. Tests of the ore were made in England before the plant was ordered. It is expected that the plant will be finished and in operation by next March.——The Palmilla cyanide plant, near Parral, is ready for operation, and that of the Veta Colorado is expected to be finished by January 15.——The West Mexican Mines, Ltd., of London, proposes to erect a 500-ton cyanide plant for the old Rosario mine at Guadalupe y Calvo. It is hoped to have the first unit in operation early next year. The ore on the dump is estimated at 170,000 tons, some assays of which show an average value of $10 per ton. The company has 10,000 acres of timber land in that part of Chihuahua.

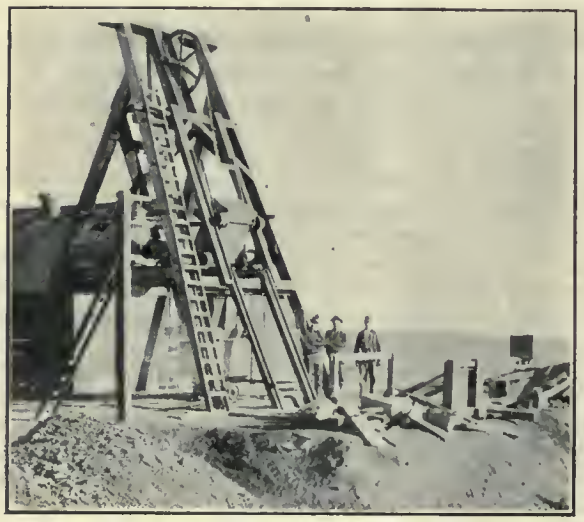
Work may be resumed soon on the project of the Guanacevi Tunnel Co., near Guanacevi, Durango. The company was formed in 1904 to drive an adit three kilometres to cut the principal veins of the district. The adit had been previously driven 1500 ft. The prospect of the Tepehuanes-Guanacevi railroad being built is creating more interest in mining in the Guanacevi district.——Enrique Schondube, of Mexico City, is at the head of an enterprise the plan of which is to build a hydro-electric plant in western Durango and transmit power to Guanacevi, Indé, El Oro, and other mining districts.——Announcement is made that the bonds of the Mexicano del Centro R. R. Co. have been placed in Paris. The project is to build a line from Camacho, on the Mexican Central, to Gomez Farias, on the National, going by way of Mazapil. A concession was granted by the State of Zacatecas for the road some time ago to Gustavo A. Madero, and a guarantee of 5% interest on the bonds necessary for 20 years was given by the State government. The plan includes the building of a branch to the Bonanza mining camp, where the American Smelters Securities Co. is operating.——F. E. Oiendorf, of the Taxco district in Guerrero, has been granted a concession by the State government for a railroad from Naranjo, on the National railway, to Taxco, a distance of 32 kilometres. Mr. Oiendorf's plans are of importance to the mining industry of Taxco district.——The National railway management is preparing to build a railroad to connect the Gulf ports of Tampico and Veracruz. The line will be 450 kilometres long, and will open the oil belt of the State of Veracruz.

PIOCHE, NEVADA

A Touch of Early History.—Restrictive Policy of Railroad Company.—Merging of Great Properties. — Problem of Handling Water in Mines.

For the first time in many months Pioche seems to warrant the interest of the mining world. Vicissitudes seem to be pertinent to the mining industry, and they have distinguished to great extent the history of Pioche district. Beginning in the earliest days, the richness and abundance of the ores found made Pioche, next to Virginia City, the most-talked-of mining camp in the world at that time. In 1876, with the collapse of the bank of California, Pioche went into eclipse, and failed to come out after that bank had been reorganized. For 25 years following that time the district has seen many bright hopes born, live a brief time, and fade into despair. It has seen many struggles, whose brilliant promise was ever doomed to disappointment. But through it all there has firmly persisted the evidence of intense mineralization, suggesting the certainty that eventually time would solve the problems and that the activity of its early days would return. Just before the San Pedro, Los Angeles & Salt Lake railroad went out on New Year's day in that awful cataclysm of flood, it looked as if the day of fulfilment was almost at hand, but that disaster left Pioche marooned for six months, during which time one after another of the mining enterprises had its wind choked off. When finally the railroad was reopened, the district was subjected to an experience without parallel in the history of Western mining development. The railroad company appeared to have conceived a violent antipathy to the region and a purpose to consistently discourage all revival of effort in it. Temporarily its accustomed train-service was restored. This consisted of a small engine, a combination baggage, express, and passenger coach, and such freight cars as the traffic made necessary. This mixed train required one engineer and fireman, a conductor, and one assistant. The entire daily cost of operating with such equipment could not have exceeded $35 for the round trip. Of course the road itself had to be maintained in order to protect the franchise. Only two mines were started at first, but the traffic was ample to furnish a profit to the system. The Pioche branch, 32 miles long, is auxiliary to the main line, intersecting it at Caliente, its function being to feed the main system, and it can properly be regarded as a part of that system. Nearly every passenger on the branch either comes from some point on the main system or goes out over the main system some distance from Caliente. The freight which passes over it furnishes part of the business of the main system. The time-card for daily service remained operative a short time and was then reduced to three times a week, and after a few days again cut down to once a week. For the last twelve Mondays, Pioche has witnessed the advent of a mixed train, and has seen the train go out. The business on the branch has been such that the

small engine had to be superseded by a large freight engine, and even this engine has been inadequate to haul all the freight, so that it has been necessary to send several specials for that purpose. When the word went out that train service on the Pioche line had been reduced to an extent hitherto unheard of in Western railroading, it put an incubus upon the camp which would have proved fatal to any mining camp of less vitality; but the material resources of Pioche are known to the mining world, and fortunately one of the greatest powers in mining has had its attention directed to the district in recent months. The result has been that the Nevada-Utah Mines & Smelters Corporation has passed under a new management. It is believed in Pioche and by the mining men of Salt Lake that the dominating influence in this new management is the same as that in the Amalgamated Copper Co., or what is generally designated as 'Standard Oil.' Ernest R. Woolley, a mining man of large experience in the West, organized the syndicate which has taken over the Nevada-Utah and has been made president and general manager for the corporation. Harry C. Parker is engineer in charge of all mining operations, and Fred R. Woolley becomes financial agent, with headquarters at Salt Lake.



Prince Con. Shaft, Pioche, Nevada.

Operations are now in progress. The Nevada-Utah company owns some of the mines on the hill which were so productive in an early day, and also what is known as the Day mine, 15 miles northwest of Pioche; also a one-half interest in the Pioche Consolidated Mining Co. The last-named company was organized last year to take over a portion of the Nevada-Utah holdings and all those of the Ohio-Kentucky Mining Co. This settled the legal controversy which had become acute between those two interests and had effectually retarded development. The Day mine has been started up again and shipments begun. The old No. 5 shaft of the Nevada-Utah has been reopened. More machinery has been ordered, and it is announced that development and production will proceed as rapidly as is consistent with real economic progress.

The announcement has been authoritatively made in New York that arrangements have been perfected for merging with the Nevada-Utah the Pioche Con. and the Prince Con. Work is now in progress on the latter, in which the shaft is being sunk to the level of the old Nevada-Utah 1200, where it is proposed to connect by cross-cut with the famous 'black ledge'. This is the name by which is known the largest deposit of ore ever found on the old hill. It is a complex ore of lead, zinc, and silver, and will require special metallurgical treatment. It is also probable that the Centennial Pioche and the Pioche King will be included in the merger now being worked out. The Centennial Pioche Co. is sinking its shaft to the horizon of the blanket deposits of its neighbor, the Prince Con., of which the main incline shaft is only about 1400 ft. distant. Work has been resumed on the Pioche King, also. The Mendha was the first to resume after the railroad was reopened, and it has been a steady shipper. The grade of Mendha ore is better now than it has ever been since the company was organized, and the management is pushing development down to the 1000-ft. level, which has been nearly reached. There are reports that the Nevada-Mendha will also join the Standard Oil combination. The promise has been made, apparently with authority, that the branch railroad will soon be constructed from the Pioche depot to the Prince mine; that a concentrating plant will be erected on the Prince side of the range; and another concentrating plant on the Pioche side, to treat the lead-zinc ores of the Consolidated Pioche. Another report is to the effect that a large smelting plant is to be erected to handle the ores of the merged mines, to treat the large tailing dumps at Bullionville, and to smelt custom ores.——One of the most interesting questions concerning development in this district relates to the underground water. In the early-day mining on the hill, water was found at a depth of 1200 ft. below the collar of the main Raymond & Ely shaft. By means of a Cornish pump this water was controlled sufficiently to enable development to be carried down to the 1500-ft. level, where was disclosed the largest body of ore yet found on the 'black ledge.' Last year water was struck in the main shaft of the Prince Con. at a horizon several hundred feet higher than the 1200-ft. level of the Raymond & Ely. Two years ago developments in the Nevada-Des Moines Mining Co.'s shaft got water at an elevation more than 500 ft. higher than the 1200 of the Raymond & Ely. Last week water was struck in the Centennial Pioche at about the same horizon as in the Prince shaft. There have been thus far no developments which furnish conclusive evidence as to the volume of water which must be handled in order to permit mining to progress. The finding of water at these different horizons indicates that there is no regular connection between the sources of the different water-levels. Should a large volume eventually be disclosed in either mine, the result would be the development of agricultural possibilities of importance. If it were not for the attitude and conduct of the railroad company, Pioche would now be coming into the limelight and many mining men would be on the ground to investigate. Under present conditions any zeal in that direction is quite effectually restrained, and we cannot look for much activity in the camp excepting such as must locally follow the rapidly expanding activities of the mines now operative. The time will come before long when the railroad will be forced to furnish adequate facilities, and when that time arrives, it is probable that Pioche will be the centre of more activity than any other mining camp in Nevada.

NEW YORK

President's Message.—Crop Statistics. — November Copper Production. — The Foreign and Domestic Consumption. — Merging of Two Arizona Mines.—Tennessee Copper Company.

The overshadowing event of the week in the financial world was the President's message. As usual, its effect had been discounted. Hardly second in importance to the message of the President is the report of James Wilson, Secretary of Agriculture, which shows that the 1910 crop totals the staggering figure of $8,926,000,000. This addition to the country's wealth will eventually have its effect on financial activity and will force the market out of the rut into which it has fallen. The report of the Copper Producers' Association, covering November, was made public this week. Figures were about what were expected. Restriction of output is showing somewhat in refinery figures. The decrease in the accumulated stocks is 8,872,845 lb. November production was 119,353,463 lb.; consumption was 128,226,308 lb.—60,801,992 to domestic consumers, and 67,424,316 for export. It will be seen that the export demand is mostly responsible for the decrease in surplus stocks. American stocks now amount to 130,389,069 lb., the smallest surplus reported since the end of March. During the eleven months of the current year the

foreign visible supply has decreased 63,197,120, making a net decrease of the world's accumulated stock of copper of 74,574,162 lb. While these figures put a much better face on the copper situation, the weak point is the fact that this improvement has been only when consumption is running at record-breaking figures. The foreign demand for metal has been unprecedented, and should it fall off, as might be expected in the natural course of business, it follows that, unless a more rigorous policy of curtailment were adopted, the surplus would almost immediately become a burden.——The consummation of the merger of the Calumet & Arizona and the Superior & Pittsburg marks the further unification of the Cole-Ryan interests. The stock of the Calumet & Arizona is to be increased from $2,500,000 to $6,500,000, its present outstanding stock being $2,000,000. The exchange is to be made on a basis of three and a half shares of Superior & Pittsburg for one of Calumet & Arizona. Stockholders are to meet April 1, 1911, to ratify the increase of capital stock and the consolidation of the two companies.——Mining bonds with conversion privileges continue to hold a degree of public favor. The recent 6% bond issue of the Tennessee Copper Co. of $1,500,000, issued to refund some $600,000 of 3-year notes and a former issue of $350,000 5% bonds has all been subscribed. Stockholders took more than 94% of the issue of the Braden Copper Co., of $1,000,000 7% second mortgage convertible bonds at par. The issue was underwritten by Eugene Meyer, Jr., & Co. The convertible special contract bonds of the Proprietary Mines Company of America have been almost absorbed. The Proprietary company has been supplying the funds to build and equip the mill on the Tajo de Dolores property at Guanajuato. This, now practically completed, is said to be the model mill of the Mexican Republic. It is to begin operating in a few weeks.——The rehabilitation of the Granby has been commenced by the declaration of a 1% dividend. This is the first disbursement made since the slump following the publication of Otto Sussmann's report early in the year. Comparisons between the unexpected exhaustion of the Granby's ore reserves and the present plight of the Utah Consolidated are heard on all sides. Granby has over $1,000,000 on hand in cash and cash assets, while the present dividend will call for but $148,496. Granby's physical condition is much improved, exploration for new orebodies has proved satisfactory, while the work on the newly acquired Hidden Creek property is showing favorably. The present management claims copper costs have been reduced lower than at any previous time in the company's history.——The Guggenheim smelting plant at Baltimore is about to lose the handling of 20,000,000 lb. of copper annually, coming from the Mt. Lyell in Australia. The firm of L. Vogelstein & Co., of New York, is interested jointly with the Mt. Lyell and Mt. Morgan Co. in the Electrolytic Refining Co., Ltd. The recently completed plant will go into operation in a few weeks, and the refinery output will be sold by the Vogelstein people. Mt. Lyell produces about 18,000,000 to 20,000,000 lb. of copper annually, the precious metal content from the same ores running about 650,000 oz. silver and 13,000 oz. gold.——An examination of the Ray Central property is to be made by W. H. Weed and F. H. Probert. The bond issue of the Ray Central has been seeking an underwriting, so far without success. The company's representatives claim some 10,000,000 tons of commercial ore proved.——It is said that the Red Metals company will be dissolved during the coming year. The entire capital stock of the company is held by the Butte Coalition Mining Co., the direct title to the Butte Coalition ground being formerly vested in the Red Metals. When the Anaconda merger was completed this title was transferred to the Anaconda and now the only asset of the Red Metals is the 500,000 shares of Anaconda received in exchange for the Butte Coalition property.

A. N. Treadgold, who has organized a dredging and power company at Dawson to operate gold dredges in the Klondike district, has had a force of 300 men in his employ part of the past season digging ditches, erecting a power plant, and putting up a pole-line for the transmission of electric power.

General Mining News

ALASKA

The report of the Alaska Treadwell Gold Mining Co. for the month ended November 15 is as follows: Mill time, 31 days. The 240-stamp mill ran 30 days, 12 hr., 18 min. Water-power, 18 days, 22 hr., 29 min.; steam-power, 11 days, 13 hr., 49 min. Ore crushed, 34,972 tons; concentrate saved, 678 tons. The 300-stamp mill, water-power, ran 26 days, 10 hr., 57 min. Ore crushed, 43,904 tons; concentrate saved, 760 tons. Total ore crushed, 78,876 tons; total concentrate, 1438 tons. Estimated gross value of free gold, $111,992.89; estimated gross value of concentrate, $75,465.05. Total, $187,457.94, less $486.85 for 130 tons of ore of United company, $186,971.09. Total realizable value, $180,277.08. Operating expenses, $94,028.86; net operating profit, $86,248.22; construction expense, $18,518.77. Yield per ton of ore milled, $2.37; stock of broken ore, 33,898 tons. Development, 417 ft. in ore, 150 ft. in waste; assay-value of ore, $1 to $8.21——Reports by men who came out of Iditarod in November are to the effect that the prices of provisions there are high, that a team of horses commanded $5 per hour, that a first-class dog for the trail brought $100. Much travel is reported between Iditarod and points on the Kuskokwim.

ARIZONA

COCONINO COUNTY

The Grand Gulch M. Co., for which W. P. Jennings of Salt Lake is manager, has shipped three cars of ore to Salt Lake valley smelters, the gross proceeds of which were about $10,000. One car sampled 4.3 oz. silver, 36.1% copper, and 5% iron. The mine is situated on the north side of Colorado canyon, and 70 miles from the nearest station on the San Pedro railroad.

GILA COUNTY

(Special Correspondence.)—The Live Oak company has started No. 39 churn-drill hole 500 ft. south and 500 ft.

Map of Arizona.

west of the vertical shaft, and No. 40 at a point 100 ft. east and 500 south. This is the shaft at which development on this property was first started. Hole No. 34, in which ore was found at 460 ft., is now down 655 ft. and is still in ore, making 195 ft. of ore averaging 2½% copper. The continuity of the orebody at this depth in this, the most southern hole sunk on the property, would indicate that the sulphide zone is of greater extent than was anticipated, and this fact results in enhancing the value of

the property. Drilling continues in holes No. 35, 36, 37, and 38. The progress in drilling No. 36 is slow, the formation here being leached schist. Its location is on the west end of the property, near the boundary of the Montezuma group. The Warrior mine continues to produce 100 tons per day of ore sampling 10% copper, which is shipped to the Old Dominion smelter. The ore consists of chrysocolla, of which this mine has proved so productive in the past. Exploration work with a churn-drill is to be started soon, with the possibility of finding the system of fissures through which the present orebody may have been deposited.

Globe, December 10.

(Special Correspondence.)—The Summit company, which purchased the Gibson claims several months ago, continues development work. The vertical shaft, sinking of which was resumed some time ago, has reached the depth of 700 ft., which is 100 ft. lower than the old workings. After cutting a station, driving will be commenced and a level established at this depth. The cross-cut, which is being driven on the 400-ft. level, has cut through the Pasquale vein, in which there is about 5 ft. of high-grade ore. This is the same vein of chalcopyrite that was discovered on the 300-ft. level from the inclined shaft. The sample mill, on which work has been progressing during the past month, is nearly complete and will be in operation within a week. Charles Myers is superintendent for the Summit company, and about 60 men are employed.

Miami, December 10.

The Old Dominion Copper Co. produced close to 2,800,000 lb. of copper in November, the average for the previous ten months of the year having been about 2,250,000 lb. per month. The mines of the United Globe, controlled by the Old Dominion, paid a floating debt of $100,000 and made a net earning of $75,000 since the first of the year. Its November and December earnings will accrue to the Old Dominion.

GRAHAM COUNTY

The November production of the mines of the Shannon Copper Co. was 1,420,000 lb. of copper, which exceeds the October output by 134,000 lb. The product for 11 months of the year amounted to 16,736,000 lb. of copper. The Shannon smelter and mill are at Clifton, the mines being situated in the vicinity of Metcalf, six miles from Clifton.

YAVAPAI COUNTY

(Special Correspondence.)—The United Verde Extension Co., operating at Jerome, is putting in a pump at the 800-ft. level, which is expected to handle the volume of water which comes into the sump at the rate of 1000 gallons per hour. J. J. Fisher is in charge.——The Snowflake, on Lynx creek, is being operated again under direction of John Harlan, who has a small force of men at work. A hoist and other machinery are being installed. This is said to be a promising gold mine.

Prescott, December 3.

CALIFORNIA

AMADOR COUNTY

The Amador Mines, Power & Water Co. has been organized at Jackson, the directors of which are W. H. Greenhalgh, R. S. Rainford, Geo. W. Brown, Richard Webb, and E. E. Endicott. The company contemplates the establishment of a storage reservoir in Grass valley, near Pine Grove, in this county, to cover an area of 150 acres; and the erection of a hydro-electric plant on Sutter creek, five miles from Jackson, to have the capacity of 2000 hp., at least half of which is expected to be used by the mining companies of this locality.

INYO COUNTY

The Casa Diablo Gold M. Co. is operating a mine and mill, situated 2½ miles from Owens river, and a short distance from Laws. According to a recent report, the mine is at an elevation 4000 ft. higher than Laws station, in a granite country. The development has been by means of one principal adit, which intersects six veins within a distance of 540 ft. These veins are well defined, but vary greatly in width. The ore is gold bearing, assaying from $4 to $40 per ton. The amount of stoping ground above the adit level varies from 50 to 400 ft. on the various veins. On one vein a 315-ft. shaft has been sunk to develop ore below the adit, two drifts having been driven in ore from the shaft. A. L. Carter, who sampled the mine, estimates 58,800 tons of ore exposed and available for milling. The equipment includes a 10-stamp mill which crushes an average of 33 tons per day. It is now planned to increase the mill capacity to 56 tons per day, by changing the stamp-drop from 88 to 95 per min., using coarser screens, and regrinding in a tube-mill, then cyaniding the product of the latter in agitating tanks. The proposed change will require a filter-press. The company has its own hydro-electric power plant on Owens river.

FRESNO COUNTY

The Davis Flat mine has been undergoing development several months. A 5-stamp mill was started last week on a supply of ore already mined. There is said to be 600 tons of ore on the dump running $10 to $12 per ton, and ore being taken from the 72-ft. shaft assays $40 to $120 per ton. The vein averages about 2 ft. in width. The property is out from Selma.

PLACER COUNTY

Peter Dick, P. J. Hurley, Henry Esmond, and others, residents of Minneapolis, have instituted foreclosure proceedings again W. J. Jean and the St. Anthony Mining & Manufacturing Co. to recover the amount of a mortgage for $4500, and they also ask that a receiver be appointed for the company. The property is in the vicinity of Auburn.

SHASTA COUNTY

The Gladstone mine, of which I. O. Jillson is superintendent, is operating with a force of 100 men. The shaft has a depth of 1700 ft., which is 700 ft. lower than the main working adit, or mill level.——The American mine, on French gulch, under option to Mr. Peale and associates, is being provided with a steam-hoist to facilitate sinking deeper.

SIERRA COUNTY

The Tightner lode at Alleghany is reported having a proved length of 260 ft., as shown by the lower adit, and has 600 ft. of stoping ground. In addition to a milling grade of gold-bearing quartz, there are found small pockets of ore containing from 2 to 100 oz. gold. The Red Star and Croesus, in the same district, are each mining rich ore. Three shipments of concentrate were made by the Croesus management during the last three months, besides the product recovered on the plates.

SISKIYOU COUNTY

The Homestake mine, situated on Taylor creek, near Yreka, has been sold by the Pluto M. Co. to R. S. Taylor at $30,000 cash. The property is in the neighborhood of the Highland mine, which was sold to The Hague syndicate last month for $250,000. Mr. Taylor's intention is to equip the mine and have it ready to begin operating next spring.

TUOLUMNE COUNTY

(Special Correspondence.)—The six claims known as the Densmore group, near Parrot's Ferry, have been bonded to William Brenner, who has commenced work with a small force of men. The property is owned and was operated for some time by the Densmore Con. Gold M. Co., composed of local people, and some shoots were opened containing high-grade ore in places.——Conlin Bros. have resumed work in the long cross-cut at the Experimental Gulch mine, above Columbia. The adit is to be 1000 ft. long and is expected to tap the vein at great depth, the objective point now being less than 300 ft. ahead.——Work will soon be resumed at the Slap Jack mine, near Groveland, after an idleness of several years caused by litigation.——It has been decided to suspend work at the Mariana copper mine, near Chinese, until next spring, when development will be resumed on a more practical plan.——

A 2-stamp mill and hoist are to be installed at the Indian mine, near Forebay, in the Jupiter district. An adit is being driven, in which is a 4-ft. vein of good-grade ore. ——It is reported that a company of San Francisco people have a bond on the Snell group of mines, in the Knight's Creek district. The property is developed by a 140-ft. shaft, from which some driving has been done.——Forty of the 100 stamps at the Shawmut mill are again in operation.——The new mill at the Tarantula mine is expected to be ready to operate within two weeks. Two 6000-gal. galvanized-iron tanks are being made for the property.—— The Marie, Patricia, and Sanford mines have been sold at referee's sale, M. E. Sanford, one of the owners, having obtained a judgment against J. D. Barber and W. H. and Sarah E. Remington. The property was purchased by the latter for $2034.11.——A shoot of rich ore is being opened in the Basin Chief mine, owned by John Daves and associates. A 16-in. streak was found containing free gold.—— The Little Beauty and Hand Over mines, near Arastraville, have been bonded to M. Tucker, a local mining man, and work has been started at the first-named claim. An adit is being driven that will tap the orebody at 100-ft. depth. The shaft on the Hand Over will be sunk 100 ft. deeper, and drifts are to be run into the 245-ft. shoot, from which ore assaying $25 to $100 per ton was taken near the surface. The vein is 18 in. wide.

Tuolumne, December 11.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A rich discovery was made last week in level No. 2 of the Josephine mine in West Argentine district. At a distance of 200 ft. from the portal 10 in. of galena is showing that brings a mill settlement of $64 per ton in silver and lead.——M. O'Hagan & Co., leasing on the Seven-Thirty mine through the Hercules level, has uncovered 10 in. of ore assaying 28% zinc and 30 oz. silver per ton. In the bottom of the winze 6 in. of ore is exposed that mills 150 oz. silver, and 30% in lead.——The Converry lease in the Capital mine has one of the richest discoveries made in recent years. Work is going on through stope No. 7 on the 190-ft. level, where there is 14 in. of solid ore that samples 6.48 oz. gold, 23 oz. silver, 68% lead, and 5.50% copper per ton. Heavy shipments are being made.——A. L. Stephens, of the Mendota Mines Co., states that a body of ore 23 in. wide has been opened at the junction of the Mendota and Tishomingo veins. Tests show from 125 to 150 oz. silver to the ton. Mining is in progress 170 ft. above the Victoria adit level.——The Rio M. Co., owning property on Sherman mountain, in close proximity to the Seven-Thirty mine, has commenced development.——The Vidler adit in East Argentine district has been advanced 4400 ft. from the eastern side of Argentine pass. The last 40 ft. was in vein material.——Lessees on the East Griffith mine have made arrangements to send a big tonnage of ore to W. E. Renshaw's Gem mill at Idaho Springs. Ericson & Co. sent out a shipment of 50 tons last week.——Work has been resumed on the Central Colorado, situated on Leavenworth mountain. E. J. Butts of Georgetown has taken those claims under bond and lease. Driving is in progress on the Central Colorado vein through the lower adit, and driving is to be started again on the upper adit.——O. W. Mann, manager of the Bellevue-Hudson property on Columbia mountain, has a force of men at work cleaning out the workings. Shipments of smelting and mill ore will be started in the next 30 days.——The Crown Prince Con. M. Co., owning a group of claims on Covode mountain, has commenced development, with F. Straub as manager.

Georgetown, December 10.

GILPIN COUNTY

(Special Correspondence.)—The Evergreen M. Co. is getting ready to begin extensive development. A new body of ore has been found at the 200-ft. level, and the shaft will be sunk another 100 ft.——The shaft on the St. Helena property has reached a depth of 40 ft., a 4-ft. vein of ore being exposed that mills $35 per ton in gold and silver. Henry Baer is owner.——The Burlington adit has been driven 200 ft., and C. D. Baer, the owner, states that a 3-ft. vein of low-grade ore is exposed.——A company is being organized to develop the National group of claims, situated on Pine creek. Work will be started soon to advance the adit, which is now in 200 feet.——A big body of medium-grade ore has been opened in the adit being driven on the Euclid vein. Tests show from $5 to $80 per ton in gold.——High-grade ore is in evidence on the 600-ft. level of the Eureka workings. The vein is 12 ft. wide, carrying ore running $5 to $10 per ton.

Central City, December 10.

LAKE COUNTY

The month of November in Leadville district was one of activity in mining and shipping ore. Within the month the Forest City, Modoc, Seneca, Modest Girl, and Agassiz, all situated on Carbonate hill, began shipping. The new shippers on Breece hill are the Bertha and Nevada; on Rock hill the Stevens shaft of the Iron Silver M. Co. began shipping. In the search for zinc-carbonate ore, the operators of the Nevada, Stevens, and Forest City found excellent bodies of lead ore, in each case the lead shoot discovered having been previously unknown in that property. Thus the interest in zinc-carbonates has served as the incentive by which comes a revival in lead mining. Doubtless there are a larger number of leases in force here than in any other district in the State, and there appears to be a good understanding between lessors and lessees. The zinc-carbonate belt is believed to extend from Fryer hill to Weston pass, and it is this phase of mining that is attracting new attention to Leadville.

SAN JUAN COUNTY

R. W. Hollis succeeds W. W. Watson as manager for the Ledge Con. M. Co. The lessees at the Ledge mine are planning the installation of an air-compressor and sinking the shaft 300 ft. below present level No. 6. The mine is north of Silverton and has a 200-ton mill.——The mine of the Iowa Gold M. Co., in Silver Lake Basin, is operating under lease to the Iowa-Tiger Lasing Co.—— Lessees on the Silver Lake mine are tramming 40 tons of ore per day from the mine in Silver Lake basin to the mill on the Animas river.——Ludwig Vota, a lessee on the Gold Bug, shipped a lot of ore to the smelter at Salida, the net returns of which were $3900. It was not a large shipment, but it sampled 192 oz. gold, and 290 oz. silver per ton. The mine is in the vicinity of Silverton. ——The Intersection, leased to D. J. Malchus, is operating at a profit. Development work is also being kept up, and the mill is being operated, the 83% saving being by amalgamation and concentration.

TELLER COUNTY

(Special Correspondence.)—The Mary McKinney mine, in Cripple Creek district, the principal workings of which

Intermediate Shaft, Cripple Creek Drainage Tunnel.

have been under lease for 18 months, is to be operated on company account after January 15. The water-level is sinking at the rate of 12 ft. per month as the result of the drainage through the Roosevelt adit. The shaft is

to be sunk 100 ft. deeper as rapidly as the water recedes, thus enabling the mine force to get at the ore almost as soon as the water is drained to that depth. The last dividend paid by the Mary McKinney M. Co. was on June 25, 1910, the amount of which was $13,092.52; total dividends to date amount to $894,363.

Anaconda, December 10.

(Special Correspondence.)—Water-level in the Portland mine has been lowered 2 ft. in the time since the watercourse was cut by the Roosevelt tunnel, and it is receding at the rate of three inches per 24 hours, although the No. 1 shaft of the Portland is two miles distant from the tunnel heading. The out-flow through the drainage adit is at the rate of 5000 gal. per minute. The high-grade ore produced by the Portland G. M. Co. is shipped to Colorado Springs and treated in the company's mill at that place, while the low-grade ore—that which runs from $2.50 to $3 per ton—is treated in its new plant at Victor. The latter is treating 8000 to 9000 tons per month, and the results of its operating have been so successful that the monthly capacity is being increased to 15,000 tons. To effect this increase a new 6-ft. Chilean mill, a set of rolls, and additional screens have been purchased, and these are to be in place and ready to operate by January 1. The milling costs at the Victor plant since July 1 have amounted to less than $2 per ton, and it is anticipated that this will be considerably reduced as the result of increasing the daily tonnage.

Victor, December 12.

The ore production of Cripple Creek mines for November, as reported by the mill managers and smelter agents, is given below, with estimates of the gross value of bullion extracted:

	Tons.	Value per ton.	Total.
Smelters	4,320	$65.00	$ 280,000
U. S. S. R. & R. Co.	15,010	22.00	330,220
Portland	10,000	20.00	200,000
Golden Cycle	24,550	20.00	491,000
Portland, Battle Mt.	8,750	3.50	30,625
Stratton's Ind.	8,000	3.00	24,000
Wild Horse	1,350	3.00	4,050
	71,980		$1,360,697

IDAHO

IDAHO COUNTY

The Del Rio M. Co. has commenced development on its group of claims on American river and Kirk's fork, near Elk City, with Peter A. Haines in charge.——A. W. Boyd, lessee of the American Eagle mine and mill, has organized a company, in which Walla Walla people have taken stock, for the purpose of operating more extensively.

LEMHI COUNTY

Butte mining men have purchased the twelve claims of the McDevitt group situated near Sunfield. The property is to be better equipped and developed. The former owners are John Rees, William Shoup, W. Gill, F. J. Cowen, F. Pattee, and W. B. Horn.——The Leadville mine, on the Junction contact, near Lemhi river, is a steady shipper of ore. The deepest workings are 200 ft. from the surface.

SHOSHONE COUNTY

The Marsh mine, situated at Burke, was purchased within the last year by a company controlled by O. L. Cowell of Missoula, J. A. White, and Pohlman Bros. of Spokane, at $150,000, the final payment of $35,000 having been made recently. During the last eight or ten months the property has been well developed under the direction of A. A. Booth. The Marsh is a lead-silver mine, having ore of shipping and milling grades.——The Shooneah group, on Coeur d'Alene divide, has been developed by 3000 ft. of work, the result of which is the opening of an ore-shoot 1000 ft. in length. It is said to be 75 ft. wide. The ore is composed of silver and lead carbonate, accompanied by tetrahedrite.——The Missoula Copper Co., operating in the vicinity of Mullan, is reported having opened a 15-ft. vein of bornite in making a raise of 20 ft. from an adit level. It is estimated that there is 700 to 1000 ft. of stoping ground in the new vein above the place of discovery. It is the intention to raise and sink on the orebody from the adit. A force of 40 men is employed on the property.

NEVADA

CLARK COUNTY

The Quartette Mining Co., operating the Quartette mine and mill at Searchlight, treated 27,468 tons of ore for the year ended September 30. The mill-heads assayed $6.59 per ton, the bullion produced having amounted to $4.34 per ton, making the extraction 66.87%. The cost of milling was $1 per ton. The main shaft is being sunk below the twelfth station, the plan being to establish the thirteenth level at 150 ft. below the twelfth. Driving on the vein is in progress on the twelfth, the present heading being about

Quartette Mine, Searchlight, Nevada.

300 ft. from the shaft. A station for pumps has been cut on the eleventh, the pumps having been moved to this station from the seventh. The ore was found 400 ft. from the shaft on the eleventh level, and has been followed by driving over 250 ft. This orebody has a width varying from a mere stringer to 20 ft. On the tenth the driving has extended 1191 ft., and stopes have been carried from this level to the ninth. The sixth level has been extended nearly 400 ft. this year, giving it a total length of about 2100 ft. The property is a gold mine, the saving being effected by amalgamation, concentration, and cyanidation. At the end of the fiscal year the company was out of debt and had a balance of $85,000 available for development and exploration.

HUMBOLDT COUNTY

The Seven Troughs Coalition Mines Co. has opened a new ore-shoot in driving 400 ft. on the fifth level from the Kindergarten shaft. The pay-ore in the shoot is three feet wide, one sample taken assaying $118 per ton. The same orebody is to be opened on the fourth level. The mill is operating with three shifts, treating the ore produced on company account and that mined by lessees on the company's property.

LANDER COUNTY

(Special Correspondence.)—The Maricopa Mines Co. has its compressor in operation and will continue the True Blue adit until the Patriot-Chase lode is intersected. The adit will have a length of 4250 ft. and will connect with the Patriot incline at a depth of 1100 ft. A good tonnage of $12 ore is stored on the dumps, and equipment for a milling plant has been ordered from Denver. F. L. Judd is manager.——The Austin-Manhattan properties at Austin are being developed and it is expected to have the mill in operation soon.——At the Pittsburg-Red Top near Kimberly a shaft is being sunk to connect with the adit. Some good ore has been extracted in which gold and silver predominate. The property is controlled by Los Angeles people. J. O. Glover is superintendent.——The Hill Top has

a deposit of rich ore in the quartzite, which occurs in small bunches.——George Wingfield has purchased three ranches, having water rights on the South Fork of the Humboldt river; his plans are to use the water for generation of power to operate the proposed reduction plant of the Buckhorn Mines Co. at Buckhorn. It is understood that a reservoir is to be formed by the construction of a dam 100 ft. high. It is rumored that the Southern Pacific contemplates building a branch line to Buckhorn.——A custom mill is in course of construction at Copper Basin abont nine miles southwest of Battle Mountain, to have a capacity of 100 tons per day; it is expected to be in operation early next spring.——The Hider-Nevada's O. K shaft discloses some copper carbonates. It is expected tha the sulphide bodies will be reached at 150 to 200 ft. deeper

Austin, November 25.

The Austin-Manhattan Con. M. Co. has built and put in operation a mill for dry concentration, which is reported doing satisfactory work. The ore is first reduced to the required fineness, then passed through a drier to eliminate the moisture. The mill is in charge of H. A. Smith, formerly at the concentrating and zinc-separating plant of the United States S. R. & M. Co., at Midvale, Utah.——The Maricopa Mines Co., whose operations are in charge of F. L. Judd, has purchased equipment in Denver for a mill to be built in New York canyon, four miles north of Austin. A crusher, rolls, tube-mill, conveyor, and boiler and engine are to be installed. The plant is to have equipment for cyaniding. A force of 32 men is employed.

NYE COUNTY

(Special Correspondence.)—The mill of the Nevada Reduction Co. has resumed operations and is treating 1200 tons from the Swander lease on the Earl.——The Shea-Putman lease on Manhattan Dexter is arranging for the immediate installation of a 50-hp. electric hoist, two 75-hp. motors, two transformers, and other electrical equipment. The machinery is on the ground.——The Francisco lease on Stray Dog has a vein of quartz running $30 to $40 per ton of gold. It ranges from 6 in. to 2 ft. wide. A stringer of rich ore is also receiving attention.——The Canon mill, operating on ore from the properties of the Manhattan Milling & Leasing Co., has been provided with additional equipment and is now in a position to treat from 40 to 50 tons per day. The new equipment includes a Bryan regrinding mill, classifiers, and an elevator. At the mine developments have been increased in order to keep the plant operating at full capacity.——In driving on the Crasp lease on April Fool ground a two-foot body of shipping ore was opened. It is planned to send some of the rich stuff to a local mill soon.——The War Eagle has concluded a run on 400 tons of ore from the Big Four Leasing Co.'s lease on the Big Four mine. The ore averaged close to $100 per ton.——The McNeil mill on Union No. 4 has been completed and is expected to commence operating within a short time. Considerable ore is developed in the mine and sufficient is on the dumps to keep the plant operating for several weeks.

Manhattan, November 30.

The Montgomery-Shoshone mine, at Rhyolite, has been closed down on the recommendation of John G. Kirchen, general manager, who stated some time ago that the property was making no profits for 1910. This mine was sold by E. A. Montgomery a few years ago to Charles M. Schwab and associates. The ore proved of lower grade than was anticipated, and the investment has been disappointing from the first.

WHITE PINE COUNTY

(Special Correspondence.)—For months past it has been rumored that the Cole-Ryan interests have purchased the Gunn-Thompson holdings of mines and water rights in this vicinity, which would seem to foreshadow the erection of a large smelting and concentrating plant for the Giroux company, which is finishing a fine equipment at the Giroux shaft. These reports have not been confirmed, but indirect details are coming to light every day. Thomas F. Cole while here recently, stated to your correspondent that the Giroux company would positively erect its plant in this district, and further that the time was not far distant when the undertaking would begin. He stated that there were some details to be worked out before definite plans were announced. Since these statements were made it would seem, by reports, that the Cole-Ryan interests are behind the merger which is now being effected at Ploche, whereby many of the mines of that famous camp are to be brought under one management. And as it is now generally believed that the billion-dollar copper merger is about to be consummated, it is apparent that the new smelter for the Ely district is to be one of the units of this giant enterprise which will stretch from the lakes to Mexico, and as far west as Nevada. With the consolidation of the mines at Pioche under Cole-Ryan management, it will naturally follow that a more direct railroad connection will be planned to connect the mines with the smelter at Ely, and it is also probable that the long talked of Salt Lake to Ely railroad will be included in the enterprise, and this would result ultimately in the construction of the Ely-Goldfield railroad which is backed by F. M. Smith and the Santa Fe railroad.——Recently this district was visited by John C. Greenway, general manager for the Calumet & Arizona and the Superior & Pittsburg mining companies of Arizona. His visit is supposed to have been in connection with the selection of a site for the proposed new plant for the Giroux company, but of this nothing has been given out, though it is known that the plant, when built, will be one of the largest and most complete in its details in the United States, and will treat lead and zinc, as well as copper, gold, and silver ores. The advent of what may be considered the Amalgamated people into the Nevada field as a competitor to the smelter trust is fraught with great interest. That their first big plant will be situated at Ely is regarded as reasonably certain, and doubtless some formal announcement to that effect will soon be made public.——The affairs of the Ely Central Copper Co. are becoming entangled in the meshes of the law. After the arrest of Scheftels and Rice, the promoters of the company, attachments were levied on the property. Finally local shareholders secured the appointment of a receiver. Attorneys for the company, which is still under the former officers, who are supposed to represent Rice, fought the appointment of a receiver, and after he was appointed they filed a suit for his removal, and also a suit asking for the removal of the attorneys representing the receiver. The court dismissed the case against the receiver, but sustained the action for the removal of the attorneys representing the receiver, on account of their having been retained for some time past by the Nevada Consolidated company, which has interests conflicting with those of the Ely Central company. The attorneys for the Ely Central company are fighting every move made by the receiver, which will prevent his accomplishing much for the company. In the meantime local stockholders have not been idle. They have an organization of which W. S. Holmquist is chairman, who has the proxy for several thousand shares of the stock. It is the purpose of the Ely stockholders to reorganize the company with assessable shares, and if possible to sell to the Nevada Consolidated company a piece of ground which controls the outlet to the Copper Pit. It is expected that this sale will net the Ely Central company from $100,000 to $150,000, which will be ample to pay off all of the company's debts and leave a considerable balance for operating expenses. Under the present plan of reorganization the company will also have several hundred thousand shares of stock which can be put on the market for development purposes. If these plans are adopted by the shareholders at a meeting soon to be held, there will yet be a hopeful future for the company, and the shareholders will not lose all of their investments as now seems probable through the pending litigation in the local courts.——The Nevada Consolidated company is arranging to use oil as fuel in one of its reverberatory furnaces, and if the experiment proves what is expected, it is probable that oil will soon take the place of coal in this district. The out-

put of the Nevada Consolidated has shown a steady falling off since July, which is in accord with curtailment of output by all of the larger companies. The company is mining on an average of 7000 tons per day, which could be increased to 10,000 tons should the occasion demand. New equipment in the way of dinkey engines and steel dump-cars are arriving, and the work of removing the overburden at Copper Pit is being rushed with vigor. The new Liberty Pit is also being rapidly opened, but will not be ready for production before next spring.

Ely, December 8.

UTAH

JUAB COUNTY

Pay-ore was discovered on the 800-ft. level of the Iron Blossom mine, Tintic district, by driving 200 ft. from the station. Bodies of ore of great width have been developed on the 400 and 500-ft. levels of this mine, and it is assumed that the ground between the 500 and 800-ft. levels will be explored with a reasonable prospect of finding profitable ore. The directors of the company, including Jesse Knight, W. L. Mangum, and J. W. Knight, are reported to be considering the advisability of building a concentrating plant. ——The Tintic Standard M. Co., manager for which is E. J. Raddatz, opened a pocket of ore on the 700-ft. level, assays running 50% lead, 17 oz. silver, and $1 in gold. The mineralization here is along a contact of limestone and porphyry. The lowest level is at 1000 ft., on which the miners are driving toward the contact. The property is situated in the north end of Tintic district.——Six cars of ore were shipped from the mine of the Chief Con. company last week, the returns from which are reported as having reached $100 per ton, gross. The mine is at Eureka.—— The Uncle Sam mine, Tintic camp, mined and marketed 30 cars of ore in November. The work is superintended by C. C. Griggs.

PIUTE COUNTY

Reuben DeWitt, operating as a lessee the Webster mine at Marysvale, has shipped two carloads of ore to a smelter in Salt Lake valley, the first one of which netted him $5100, and the second $4453. The second lot sampled 8.8 oz. gold and 57 oz. silver per ton.

SALT LAKE COUNTY

The American Exploration Co., managed by F. V. Bodfish of Salt Lake, besides taking control of the American Flag mine at Park City, has acquired oil land in San Juan county, on which it has an oil well called the Arcola which produces oil that resembles the Pennsylvania product.

SUMMIT COUNTY

The Virginia M. Co. has been organized to operate the mine of the C. C. Consolidated M. Co., in Thane canyon, near Park City, by E. P. Evans and associates. The new company has a 10-months lease on the property, and holds an option on 370,000 shares of the C. C. Con. M. Co. The mine is well developed, and the ores carry silver, lead, and copper. In one part of the mine is a large body of zinc ore. ——Tests for concentrating the slime are being made in the basement of the Daly-Judge mill. The ores of the Daly-Judge mine contain silver, lead, and zinc. As a rule much of the zinc ore may be mined separately, though all of the silver-lead ore contains some zinc. Experiments in concentrating the zinc ore are being made with the MacQuisten tubes, the work of which is the reverse of gravity concentration. The process is being demonstrated at the testing plant of the General Engineering Co., Salt Lake. An important event the past month in Park City was the completion of a drainage connection between the Daly West and Daly-Judge workings. The November production of the latter amounted to 4253 mine cars of milling ore and 480 mine cars of shipping ore.——The Snake Creek Tunnel Co., which is driving a drainage adit from the Wasatch county side of the range into the heart of the Park City district, drove 333 ft. in November, making a total distance of 2068 ft. When finished the tunnel's length will be over 14,000 feet.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

TITLE TO COAL OWNERSHIP OF SURFACE

The ownership and possession of the surface land does not carry with it the possession of coal underneath such surface, where the estate in the coal had been previously severed as to title. And the surface owner, in order to claim proper possession of coal severed in title from the surface land, must show that he has had actual physical possession of the coal, apart from his possesion of the surface, such as by operating mines.

Plant *v.* Humphries, (W. Va.) 66 Southeast. 94. Nov. '09.

ADVERSE MINING CLAIM IN PHILIPPINE ISLANDS

An adverse mining claim sufficient to defeat the right to a patent under the United States statute, where natives and their ancestors have held possession and worked such claims in the Philippine Islands for the statutory period, cannot be based on entry and staking of a claim and filing notice of location, where such possession was continuous to the time of bringing an action to restrain the persons relying upon such acts as amounting to an adverse claim from setting up title or interfering witn the claims.

Reavis *v.* Fianza, 30 Sup. Ct. Rep. 1. Nov. '09.

PAYMENT BY MINING COMPANY FOR LABOR—EFFECT AS RATIFICATION

The payment by a mining company of certain claims for labor performed, on or in connection with its property, under employment of a third person, was held not to amount to an adoption or ratification, or even a recognition, of the claims of other laborers for services performed for such third person under similar circumstances and at the same time as the claims paid by such mining company, where the services had all been performed prior to such payment.

Linn *v.* Almeda Mining & Milling Co., (Idaho) 104 Pac. 668. Oct. '09.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE

A miner purchased from his employer a fuse with which to set off a charge of dynamite in his employer's mine. On being properly lighted the fuse failed to burn and smoke in the usual manner, and thereupon the miner supposing that it had gone out, frazzled the end of it and again applied the blaze, and on its falling to fuse again, repeated the operation, and thereupon an explosion immediately followed and the miner was injured. In an action by the miner for the injuries, it was held that his complaint was insufficient, as he was not warranted in assuming that the fuse was defective because it failed to smoke, and that he was guilty of contributory negligence in remaining so near after first lighting it.

Cody *v.* Norton Coal Co., (Va.) 66 Southeast. 33. Nov. '09.

MINING CLAIM—ABANDONMENT—SECOND LOCATION

Mineral ground covered by a valid location thereby becomes segregated from the public domain and is the property of the locator, and so long as he complies with the State and the United States laws and location regulations he has the exclusive right and enjoyment of all the surface included within the lines of the location; and during such time the ground so segregated is not open to location by another. However, grounds embraced in a mining location may become a part of the public domain, so as to be subject to another location before expiration of the statutory period for performing the annual labor, if at the time of making the subsequent location there had been an actual abandonment of the claim by the first locator; but at the time of such subsequent location, the ground must be open to location under the mineral laws of the United States.

Swanson v. Kettler, (Idaho) 105 Pac. 1059. Jan. '10.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

TRACK FORMULAE AND TABLES. By Shelby S. Roberts. Pp. 514. Ill., index. John Wiley & Sons, New York; Chapman & Hall, London, 1910. Bound in black morocco flexible cover. Price $3.

This is a new volume, in pocket size, and clearly printed. It presents in a practical manner the track problems encountered daily by the engineer in his work on railroads. Curves, frogs, and switches are treated in a concise manner, and many new and useful suggestions are made to the young engineer and student. There are carefully compiled tables and formulas, which make the book of practical value.

COMPRESSED AIR PLANT. By Robert Peele. Pp. 502. Index. Ill. John Wiley & Sons, New York. $3.50.

This is the second edition of Mr. Peele's noted work, revised and enlarged, having had 174 pages and 97 figures added to the original. It deals with the production, transmission, and use of compressed air, with particular reference to its application to mining. Several tables have been prepared of the detailed records of work performed by machine-drills, which will be useful. There is also added 90 pages descriptive of various machine drills and their operation. It is a work which cannot fail to be of value to all users of compressed air at mines.

GUIA MINERA PARA INGENIEROS Y PRACTICOS. By Ferdinand McCann. Pp. 522. Index. Published by the author, City of Mexico, D. F. Price $6.

This volume is one of the most helpful publications in the Spanish language that has recently been issued. It is primarily intended for the use of engineers whose operations are being conducted in Mexico or other Spanish-speaking countries. It contains many handy conversion tables, including those employed in converting the metric system to English; tables of equivalents, measures, and weights; value of various metals in English and American money; assay tables; and many others found in engineering books in the English language, including circles, natural sines and cosines, logarithms, and trigonometric functions. A chapter on mining terms, and one on Mexican mining law, add much to the value of the volume. It is handsomely bound in flexible morocco cover.

PRACTICAL STAMP MILLING AND AMALGAMATION. By H. W. MacFarren. Pp. 166 Index. *Mining and Scientific Press*, San Francisco; *The Mining Magazine*, London, 1910. Price $2.

This book has evidently been written by a man who has been 'through the mill' in every sense of the word. The subject matter covers stamp-mill operation rather than stamp-mill construction, although much that is of interest and value to prospective mill buyers will be found within its pages. Every possible condition and emergency incident to the operation of stamp-mills has been thoroughly covered, and the subject matter is clearly written in simple language, free from needless technicalities, making this book of exceptional value to young men desiring to qualify as mill operators or amalgamators. Even the old-time millman will find much of interest and value within its pages, and no one, whether he be a mining engineer of the highest attainments or an underground shoveler with ambitions to rise, should be without this book. Much has been written on the subject, but never before have the principles, theory, and practice of stamp milling and amalgamating free milling gold ores been so simply and clearly set forth. The book is divided into three parts: Part I, Stamp Mills; Part II, Amalgamation; and Part III, General Comments. The chapters on reports, milling tests, and related topics are particularly pertinent at this time when the old rule of thumb methods of mill operation are being rapidly succeeded by the most careful and accurate systems of sampling and accounting. The index is exceptionally good, and greatly facilitates ready reference to data on the problems of the moment. C. J. H.

Recent Publications

PRODUCTION OF TALC AND SOAPSTONE IN 1909. By J. S. Diller. U. S. Geol. Surv. Adv. Chap. Min. Res. Pp. 11. Washington, 1910.

THE TECHNICAL CONTROL OF THE COLLOID MATTER IN CLAYS. By Harrison E. Ashley. From Trans. Amer. Ceramic Soc. Vol. XII. Feb. 1910.

A CELLULAR REINFORCED-CONCRETE DAM. By George J. Bancroft. From proceedings Colo. Sci. Soc. The author proposes a form of dam construction which is a departure from ordinary practice.

PETROLEUM AND NATURAL GAS. By A. G. Leonard, H. E. Gregory, C. W. Washburne, and Robert Anderson. U. S. Geol. Surv. Advance chapter from Contributions to Economic Geology, 1909. Part II, Mineral Fuels. Washington, 1910.

BIBLIOGRAPHY OF NORTH AMERICAN GEOLOGY FOR 1909, with subject index. By John M. Nickles. U. S. Geol. Surv. Bull. 444. Pp. 174. Washington, 1910. A concise list of books and other contributions having a bearing on North American geology.

COLORADO SCHOOL OF MINES MAGAZINE, October 1910. The Colo. S. of M. Alumni Assn., publishers. Golden, Colo. By F. W. Traphagen. Contains a description of the new ore-dressing and metallurgical experiment plant of Colorado School of Mines.

MINING IN JAPAN, PAST AND PRESENT. Published by the Bureau of Mines, the Department of Agriculture and Commerce of Japan. Pp. 322. Ill. and maps. Tokio, 1909. An interesting exposition of the mineral industry of Japan, its history, development, and present condition.

GEOLOGY AND ORE DEPOSITS OF REPUBLIC MINING DISTRICT. By Joseph B. Umpleby. Geol. Surv. of Washington. Bull. No. 1. Pp. 65. Ill., maps, index. Seattle, Wash., 1910. Contains a comprehensive description of the geology, mineralogy, and mining operations in Republic district.

RESULTS OF TRIANGULATION AND PRIMARY TRAVERSE, for the years 1906, 1907, and 1908. R. B. Marshall, Chief Geographer, U. S. Geol. Surv. Bull. 440. Pp. 688. Index. Washington, D. C., 1910. The usual statement of progress of triangulation, which is the preliminary basis of the great Geologic Atlas of the United States.

GEOLOGY AND MINERAL RESOURCES OF THE SOLOMON AND CASADEPAGA QUADRANGLES, SEWARD PENINSULA, ALASKA. By Philip S. Smith. U. S. Geol. Surv. Bull. 433. Pp. 234. Ill., maps, index. Washington, 1910. An interesting description of the geology and mineral resources of a portion of the Seward Peninsula, including the veins and placer deposits, with a chapter on dredging.

THE AGENCY OF MANGANESE IN THE SUPERFICIAL ALTERATION AND SECONDARY ENRICHMENT OF GOLD-DEPOSITS IN THE UNITED STATES. By William H. Emmons. Reprint from Trans. Amer. Inst. Min. Eng., 1910. Comprehensive discussion of the effect of manganese on the dissolution and reprecipitation of gold in veins, showing important bearings on problems of ore genesis and exploration.

GEOLOGY OF THE HALIBURTON AND BANCROFT AREAS, PROVINCE OF ONTARIO, CANADA. By Frank D. Adams and Alfred E. Barlow. Memoir No. 6, Canada Department of Mines. Pp. 419. Ill. Index. Ottawa, 1910. The region described in this interesting volume is entirely Archean, but the structure is complex. Many varieties of rock exist there, and metamorphism is pronounced, as it usually is in Archean areas. Much of the region has been reduced to a broad penepiain by the great ice sheet. Considerable space is given to a study of the petrology of the region and also to its economic resources.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. Finch is at Butte, Montana.

Bayliss S. Clark was in San Francisco.

O. Bergstrom was in San Francisco Tuesday.

Charles Janin has gone to Oroville and Folsom.

Ralph Arnold was in San Francisco Wednesday.

J. A. Burgess was in San Francisco Monday last.

C. W. Purington is at St. Petersburg temporarily.

F. Lynwood Garrison was in San Francisco this week.

A. F. Main has returned to El Oro, Mexico, from a trip abroad.

F. W. Bradley has returned to San Francisco from New York.

W. S. Noyes has returned to San Francisco from Shafter, Texas.

E. B. Kirby left San Francisco for St. Louis, Missouri, this week.

J. P. Hutchins sailed from New York for London, December 8.

Robert McCart, Jr., is general manager for the Indé Gold M. Co., Durango, Mexico.

Donald B. Gillies has returned to Santa Eulalia, Mexico, from a trip to the United States.

George A. Schroter is inspecting the properties of the Mines Company of America, in Mexico.

R. C. Kline is studying the ore of the Boulder Creek Co., of San Diego county to devise treatment plans.

Frederick G. Clapp has taken new offices in the Fitzsimmons building, 331 Fourth avenue, Pittsburg, Pennsylvania.

F. H. Probert returned to Los Angeles from the Superior & Boston mine at Globe, and left immedately for Ray, Arizona.

L. D. Godshall has tendered his resignation as manager for the Needles Mining & Smelting Co., to take effect December 31.

I. L. Merrill, president of the Hedley Gold M. Co., recently inspected the properties of the company at Hedley, British Columbia.

C. M. Fassett, president of the C. M. Fassett Co., Spokane, assayers and metallurgists, was in San Francisco, on his way to the Orient.

Emil Melzer, former manager at the North Pole mine and mill, Baker county, Oregon, has been visiting the Treadwell mines in Alaska.

L. C. Snider has been appointed assistant director of the Oklahoma Geological Survey, and Frank Buttrum has taken his place as chemist.

W. A. Stevens, of San Francisco, is developing a mining property near Hope, British Columbia, for the Steamboat Mountain Gold Mines Company.

A. H. Adams has resigned from the service of the Tonopah Extension M. Co., to become mill superintendent for the Geo. F. Roth M. Co., Neai, Idaho.

G. H. Carnahan, formerly manager for the Montezuma Lead Co., at Santa Barbara, Chihuahua, is in charge of the mining operations of the Mexican Metallurgical Co. at San Luis Potosi.

Thomas Neilson has entered into partnership with L. Morgan under the name of Morgan & Neilson, as assayers and analytical chemists, with an office at 319 South Spring street, Los Angeles.

D. A. McMillen, mining geologist, and consulting engineer for the Barney Copper Co. and the Globe Bureau of Mines, is on an extended trip to New York, Boston, and other Eastern points.

TABLE OF CONTENTS

EDITORIAL

WE join the attractive young lady on our front cover in wishing our readers a Merry Christmas. May the grade of your ore increase and your extraction never grow less!

ELECTRICITY is to be applied to drilling oil-wells at Coalinga. In this, as in other work where a reciprocating motion is desired and where inequality of load is important, application of electricity has been slow. The great advantages incident to the ease of installation and distribution of power are slowly leading to changes. The work at Coalinga will be watched with much interest.

NEW copper production in 1911 seems certain to be large and many estimates are being made. In the *News Letter* circulated by Thompson, Towle & Company, Miami and Ray are credited with a possible 30,000,000 pounds, Chino with 15,000,000, and Utah Copper with an additional 20,000,000. This amount would not seriously disturb conditions, but others place the probable output higher. In the East it seems to be generally held that the California smelters will not overcome smoke difficulties in time to make large outputs next year; for our own part we have more faith in the ability of the men in charge to overcome even the admittedly great difficulties that now hamper production.

JAPAN and its mineral resources have been described recently in a most instructive handbook issued by the Bureau of Mines at Tokyo. We are indebted to Mr. Manji Yoshimura of that Bureau for a much appreciated copy, and we present this week a brief abstract from the chapter in which gold deposits are described. The mineral output of Japan now amounts to approximately $60,000,000 per annum, with coal, copper, and petroleum leading in production. The country is one of great interest, in that very ancient as well as most modern methods of mining and treatment may be seen in use. It is also one of large possibilities, and accurate information such as this handbook contains is welcome.

TESTS of many kinds are needed in order to develop and to improve engineering practice. In a recent paper on 'The Crushing Strength of Coal,' appearing in the *Proceedings* of the Sydney Engineering Society, Mr. Arthur Jarman, professor of mining engineering in University College, Auckland, New Zealand, has assembled and discussed existing data available for determining the proper size of pillars in coal mines. On the whole, it is apparent that the data are entirely inadequate. In general, such tests have been made on small pieces only, though in

Pennsylvania a few large cubes of anthracite, and in Illinois, similar blocks of bituminous coal, have been crushed. Even less data are available to engineers of metal mines. At Johannesburg some tests have been made, but in general the figures available are those obtained from studies of building stones. At the Pittsburg Station of the U. S. Bureau of Mines there is a 600,000-pound machine ready for use and a 10,000,000-pound machine that has never been erected. It would be extremely interesting to have the results of a really adequate series of tests made on these large machines.

AUSTRALIA is a country where effort to aid industry through Governmental action has gone to lengths that are frequently criticized. That there is much good, even if possibly some harm, in the friendly paternalism of the Australian States is indicated by the account of the mining situation in Western Australia written by Mr. A. Montgomery, the State Engineer, appearing on another page. It is also interesting to note that according to *The Australian Standard* the Federal Government has under consideration payment of bounties to stimulate production of oil from shale to safeguard the naval fuel supply. In the United States it has been hard enough to get the navy to adopt petroleum, despite its abundance, and a bounty is unthinkable.

Location and Annual Labor

On or about the first of January of each year prospectors and others throughout the mining regions of the West have long made it a practice to locate new mining claims, or to re-locate old ones. In view of this fact, a few suggestions will perhaps be timely, particularly to those not familiar with the laws governing the location of mining ground on the public domain.

The first requisite in the location of a mining claim is an actual discovery of valuable ore, or mineral, 'in place'—that is, not detached from the vein or mass in which it originally occurred. Having found the 'valuable mineral,' the next step is to post a 'notice of discovery' at the point where it was found. This notice should state clearly the length claimed along the lode, or vein, in each direction from the discovery point, and the width of ground claimed on each side of the centre line of the vein, which is supposed to run through the centre of the claim. The length of any one claim can not exceed 1500 feet, nor may its total width be greater than 600 feet, 300 on each side of the centre line. The locator should state in his notice that he claims the statutory time within which to perfect his location. The next step is to mark carefully the corners of the claim by stakes, or monuments of stone, or both, so that the boundaries may be easily traced. Often the prospector, or claim locator, purposely neglects properly to define the boundaries of his claim, seeming to think obscurity as to the definite limitations will serve some useful purpose. No greater mistake can be made. It is quite likely that if the claim is of no value, and no very valuable ore is discovered, the locator will remain unmolested in his possession till doomsday; but let rich ore be found and attention is at once attracted. Then many become eager to oust the locator and take the claim. If the ground is to prove valuable, its discoverer can not too thoroughly safeguard his title by exact and painstaking compliance with the requirements of the law. Mark the boundaries clearly and substantially, not only by blazing trees, or building a little monument of stones, but by good-sized monuments and stakes, indicating each corner plainly. Having located the claim, begin work upon it at once and endeavor to do the equivalent of a year's assessment work; that is, one hundred dollars' worth. This is usually taken to be a ten-foot hole. The Federal law does not demand this, but in several States the laws do require a stated amount of labor within 60 to 90 days, this being required as a part of the act of location; and a wise law it is, since it prevents a certain class of men from staking scores of claims in new districts and holding large areas against all others while doing nothing to develop or improve the claims.

As to assessment work, all unpatented claims upon which the annual labor has not been performed in the year 1910, except such as have been located within that year, are open to re-location at midnight, December 31, 1910, by anyone except the original locator. The latter may go upon the ground at the last minute, so to speak, and by resuming work and continuing it until the hundred dollars' worth has been actually completed, save his claims from being appropriated or 'jumped' by others. This point in law has been passed upon by the courts of several States, and by the Supreme Court of the United States. For every claim taken, a separate discovery, on that claim, is necessary. A single discovery will not hold a group of claims. After discovery and location, a copy of the certificate of location should be placed on record, with the local recorder, if there be one, and also, for safety, with the recorder of the county in which the claim is situated. If there be no local recorder, then the notice should be filed with the county recorder. When annual labor has been completed, notice to that effect should be posted on the claim and a copy of this notice placed on record with the local and county recorders.

If it be discovered after making a location, that a mistake has been made, and that, for instance, the vein does not run in the direction at first supposed, but crosses a side-line, an amended location may be made, and the lines of the claim swung around so as to cover the vein properly; provided no one has located the ground adjoining the claim since the date of location. In that event the original locator will be unable to move the corners of his claim. That becomes his misfortune, but the law makes no provision for such shortsighted errors of judgment. Locate with the vein, laying the side-lines parallel with the outcrop, and by all means see that the end-lines are parallel so as to secure full extralateral rights.

The Clifton-Morenci Diistrct of Arizona—II

By William L. Tovote

MINING METHODS

The three most important mining companies operating in the Clifton-Morenci district are, in order of their production: (1) the Arizona Copper Co., Ltd., of Clifton and Edinburgh, to which I shall refer as A. C.; (2) the Detroit Copper Mining Co., of Arizona, a Phelps-Dodge concern (D. C.); (3) the Shannon Copper Co. (Sh. C.).

The A. C. operates near Metcalf three producing mines, besides several smaller properties and prospects. The large mines are the Metcalf, King, and Coronado. The King mine is on a fissure vein in porphyry. The ore is practically confined to the vein itself except where the Jamieson lode crosses it, where great disseminated orebodies have formed near the intersection. The Coronado is a fault-fissure in granite, with a diabase intrusion, and resembles the King, as mineralization is practically confined to the vein, and well defined walls separate the ore from the country-rock. The Metcalf mine resembles the Copper mountain type at Morenci—disseminated orebodies arranged in lodes—but the porphyry is somewhat more silicious, being consequently harder and less friable. The ground is not nearly as heavy as that in Copper mountain. P. B. Scottland, superintendent at Metcalf, has introduced stoping methods that are similar to those practised at Nacozari, though improved and adapted to meet local conditions. The change to modern working methods was rendered difficult, as the mines of Metcalf district had been worked in the old-fashioned way, lacking in system, and with little regard to the future. The use of steam-shovels was carefully considered, but the idea was abandoned for the reason that the orebodies were too badly cut up, the richest parts, and those which would have been most easy of access, having been mined, leaving the leaner parts and those covered with heavy overburden. Underground mining had been by either square-setting or open stoping. At present there are mainly two stoping methods, both practically dispensing with timbering and at the same time much safer than the old method of open stoping.

1. **Mining and filling.**—The orebody is worked in ascending slices, each about 20 ft. high. A slice is mined and the stope cleaned out. Then waste is run in from above and leveled off, leaving about 5 ft. open space between the back and the fill, enabling the men to attack the next slice. Raises and a haulage road are maintained by timbering. Some of the Metcalf hill orebodies are close to the surface and the waste mined for filling helps to strip the overburden from these upper orebodies, and thus permits mining this ore by open-cutting, that otherwise could not be stripped and mined in that way at a profit.

2. **Stoping on top of broken ore.**—The character of the Coronado and King veins, with their well defined walls, allows a simple method of mining. Stopes are laid out 50 to 75 ft. in length along the vein; sometimes two of these stopes, with a 10-ft. pillar between them, are worked as a unit. The ore is broken over the whole width of the vein, 25 to 40 ft. wide, and enough drawn or shoveled out to allow working space on top of the broken ore which is left in the stope. The men work on top of the broken ore. Drilling is done by machines almost exclusively, and all the holes are 'uppers.' After the stope has been started on the sill-floor, hammer-machines of the Shaw or Waugh type, or others, do all the drilling, as practically all holes are 'uppers.' For block-holing big boulders, the small hammer-machine patented by C. Holquist is used. This machine is only about 1½ ft. long over all, has a sort of saw-handle, and uses perforated octagonal steel. In the handle is a spring valve that, if pressed, turns the air through the perforated steel, blowing out the drillings. The stope is started, either on the level and the ore shoveled out from lateral shovelways, or the bottom part of the stope is filled with waste 15 to 20 ft. high, chutes and haulage roads being first provided for by timbering, or the stope is started 20 ft. above the level and chute-raises carried up to it, preferably from a lateral haulage road outside of the vein. The distance between chutes, or shovelways, is about 25 ft., centre to centre. If the stope is carried up to an old waste-filled stope above, the latter is tapped after all ore is cleaned out of the stope beneath and waste is run in. The costs of these stoping methods I should estimate roughly to be between 30 and 35c. per ton of ore, delivered at the shaft, or at the ore-bin in case the ore is sent to the surface through an adit. For loading the ore into mine-cars at the shovelways, loading machines such as have been tried, though not with great success, in coal mining, might perhaps be applied successfully, as much of it is shoveled practically from the same place, the ore running to it by gravity. The disadvantage of the loader in coal mining was to a great extent due to the necessity of shifting the machine frequently, owing to the widely scattered broken coal, no large amount being readily obtainable at one place.

The mining methods employed in the Clifton-Morenci district are principally open-stoping, square-setting, and caving.

Open stoping is, and was, done both as surface open-cutting and underground open-stoping. It was apparently the chief method of working the metasomatic orebodies occurring in limestone and shale. Favored by a country-rock that stands well, these open stopes necessitated little timbering, and some of them are today open and in good condition, after years of abandonment. Surface open stopes are still worked to some extent at Shannon and Metcalf hills, and at the A. C. company's Queen mine, though it is idle at present. In these places the oxidized orebodies started practically at the surface, as was the case with the great Longfellow orebody, at Morenci, which attracted attention to the district. These surface orebodies are tapped by chute-raises

from adits. The broken ore descends through these. In the course of development these irregular little adits are more and more reduced to distinct levels. In places the open-cuts have descended to, or even passed, these levels. In the first case, the ore is shoveled into cars where it was broken, easily-shifted track with light steel rails being kept at all times close to the working breast. Elsewhere the surface workings are connected with the highest underground level, and the ore is drawn from the open-cuts through chutes down to it. The ore is broken with deep holes, sunk with jumper-drills, sprung with dynamite, and blasted with black powder. A great amount of ore has been mined for years from

Fig. 1. Looking Down on Metcalf, Ariz., From Top of Coronado Incline.

these surface orebodies, and its further removal requires the stripping of an ever-increasing amount of overburden. This waste rock is either milled down into the mine and utilized as filling, or is disposed of in waste dumps on the surface. Shannon and Metcalf hills are honeycombed with these great open-cuts. Some of those which started as separate cuts have extended into each other, widening here and narrowing there, up to several hundred feet in length. These holes, and the accompanying waste dumps, have changed the original topography of the hills greatly. The surface open-cuts gave rise to an important feature of mining in the district. I refer to the surface-inclined tramways for handling ore by gravity. While the incline is very commonly used underground in coal mining in Europe, I never saw it developed to such an extent on the surface as has been done here. These inclines have either double track, or three rails, with a four-rail switch in the middle. The loaded car going down by gravity, pulls up the empty, or a car loaded with materials. Round, steel-wire ropes and cylindrical drums are used. The operation of the cars is controlled by brakes. The most prominent inclines are: the Coronado, 3200 ft. long on the incline and 1300 ft. high; the Shannon, the steepest in the district, being on a slope angle of 35°; and the Longfellow. The Longfellow incline handles the heaviest traffic. It is 2800 ft. long, with an average dip of about 17°. The upper 500 ft. is built on a steel trestle. The cargo handled, going down, includes the output of all the A. C.'s Morenci mines, except the Longfellow, as concentrate, first-class ore, or pyrite for the sulphuric-acid plants, and limestone and quartz ores for flux and converter lining, together with the limestone for the Shannon and A. C. smelters. The upgoing materials are, mine-timbers, machinery, and all merchandise for the A. C. Longfellow store. Coal used to constitute a great

Fig. 2. Caved Square-Set Stope, Arizona Copper Co., Morenci.

deal of the cargo till the A. C. changed its plant so as to burn oil.

Square-setting.—This method of timbering, while applied in some of the metasomatic orebodies, came into prominence with the opening of the porphyritic deposits. The Morenci square-set is the simplest of all in use here. The standard set consists of the following: (1) round post, 10 to 12 in. diam., 6 ft. 8 in. long over all, with horns 5½ in. square, 6 in. long on top, and 2 in. on the bottom; (2) cap (square), 8 in. by 8 in. section by 5 ft. 2½ in. long; (3) round girt, 5 ft. 2½ in. long, 10 in. diam., trimmed 1¼ by 1¼ in. on the sides at the ends to form a tenon 8 in. high. The details of timber framing for square-sets are shown in Fig. 3. Square-setting is employed as a rule in overhand stoping with subsequent filling, but has been tried also by the D. C. in heavy ground with underhand stoping. Large overhand stopes have been worked by this method, especially by the A. C., and while they were welcomed in earlier days, some of them must have proved rather expensive recently, as large areas of the country around the larger mines have begun to settle. This is increasing at an alarming rate in Copper mountain, around the Yankie and Longfellow mines, and will affect the town of Morenci as well as its mines. Some of the largest square-set stopes in the district

were laid out on the second level of the Humboldt mine of the A. C. Here the attempt was made to mine in one stope the whole width of the Humboldt lode at its widest part, near the Copper mountain fault. The ground was laid out in alternating blocks each 7 sets wide. The length of the blocks in places was 60 odd sets (the width of lode). The intermediate blocks are to be milled down by caving, after the original block stopes have been carried up to the waste line. Whether this will be a success remains to be seen. The conditions are ideal, if only the waste in the filled stopes can be kept from running. This method of block-stoping is illustrated in Fig. 4.

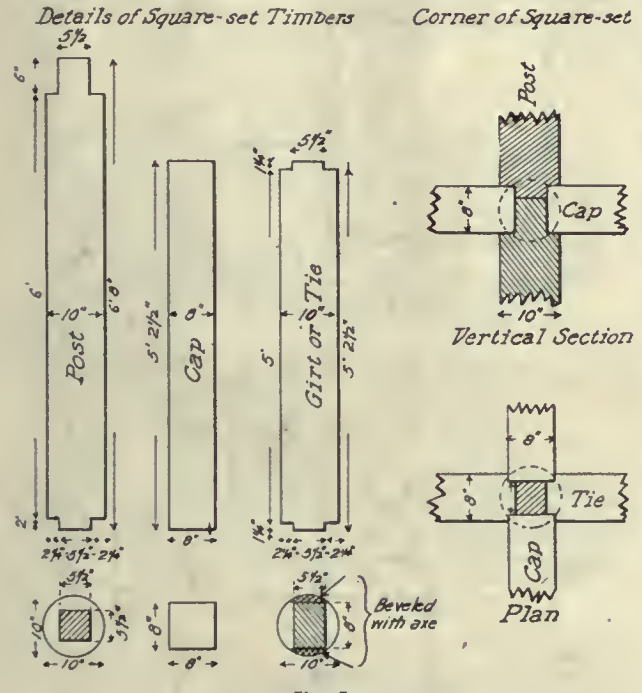

Fig. 3.

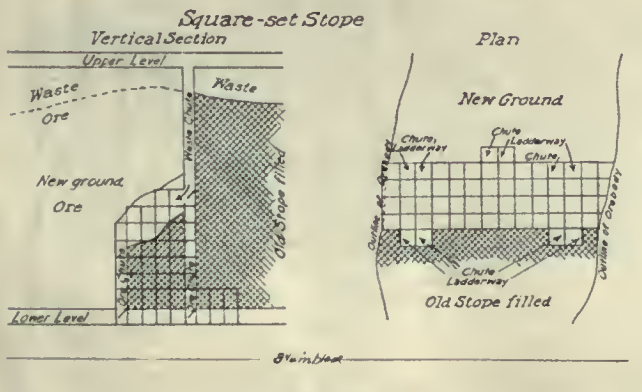

Fig. 4.

The D. C. has within recent years changed its mining methods almost completely from square-setting to caving. Where ground has, of late, been square set, it has been mined in smaller sections. In heavy ground the stopes are laid out three sets wide, and in good ground five sets seem to be the limit of width, except in some early stopes. Where the lodes converge or widen the whole width of the lode is not taken out in one stope, but it is subdivided into blocks. It has proved practicable to place chutes and ladderways in the last row of sets at the side of the block and adjacent to the new ground, or even outside of the stope proper. In this way the chutes and ladderways can be utilized again in stoping the next block. This practice has been especially helpful wherever underhand square-setting has been resorted to. In underhand square-setting the least possible area of ground is kept open. The mined-out set is tightly floor-lagged and carefully hand-filled as soon as the necessary working-space permits. Several floors can be worked at the same time, as a new floor can be started as soon as a part of the upper one is completely filled, and it is advisable to keep the work well concentrated and not to start too many floors at the same time. Owing to the necessity of hand-filling, floor-lagging, and more difficult timbering, underhand stoping is more expensive than overhand work. The method is applied principally to heavy ground where the grade of ore warrants the additional expense. Waste for filling is mined in large surface pits at a cost of perhaps 5c. per ton of ore mined. Originally this cost must have been higher, as the cap-rock is about 150 ft. in thickness. These cuts have advanced so far downward that the A. C. is now mining some high-grade chalcocite in the waste pits which pays part of the cost of filling. The waste resulting from development and dead work is practically negligible in comparison with the tonnage of ore mined, most of the development being done in ore. The scheme of block-caving is illustrated by Fig. 5, which shows the general plan of the level, a vertical cross-section, B, and the plan of three floors, A.

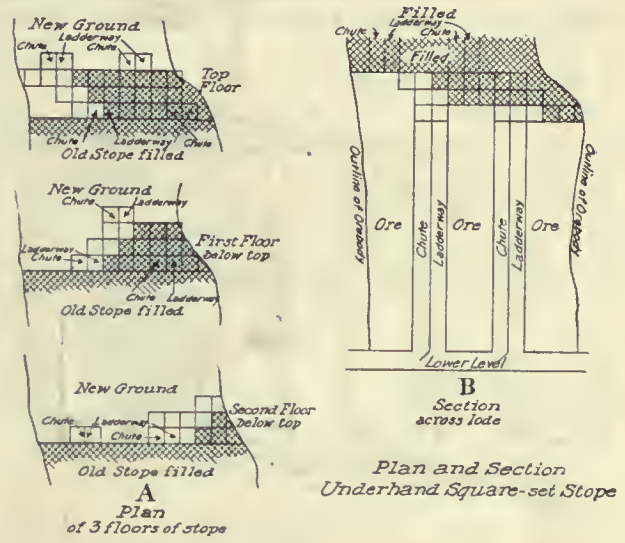

Fig. 5.

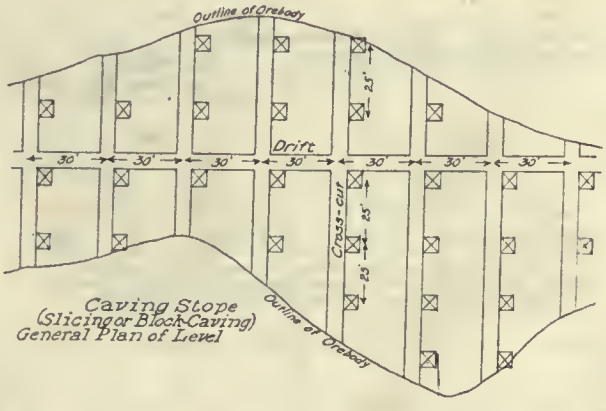

The ore of the district is rather light, being chiefly a mixture of aluminum and magnesium, clay, and quartz with a slight admixture of pyrite and chalcocite, or oxidized copper minerals. The specific gravity will probably average near 3, or possibly less. Engineers figure that 12 to 13 cu. ft. in place, or 18 cu. ft. broken, equals 1 ton, or the content of one square-set approximates 20 tons.

Caving Methods.—The increasing heaviness of the ground, and the consequent greater difficulty and cost in carrying up square-set stopes, caused the D. C. to search for other methods of mining its ore-bodies. It was decided to adopt caving methods, as they have been developed in the iron mines in the Lake Superior region. The change was initiated during the time of high copper prices, so that the sudden slump which occurred later found the D. C. well prepared to meet this emergency. The methods employed at Morenci are those known as block-caving and slicing. P. B. Scottland, superintendent for the A. C. at Metcalf, has introduced other methods of stoping on lines somewhat similar to those in use at Nacozari, Mexico, and, favored by natural conditions, his mining cost is probably the cheapest in the district. Stoping in Morenci extends vertically, as a rule, through two, sometimes three (seldom more) levels. The standard distance between the floors of the levels is 100 ft., some of the older levels having less, and very few having more. When laying out caving stopes the stope-area is opened on the highest level by drifts and cross-cuts, and then raises are started at convenient intervals. It has been found that 30 ft. between cross-cuts and 25 ft. between raises, along these cross-cuts, measured centre to centre, affords ample shoveling facilities. The raises are carried to the top of the ore. For slicing stopes, the top of the ore is usually mined by square-setting, one or two sets high, and without filling. The floor is covered with lagging and old timber, the raises are secured by covering over and bulkheading. Then the timber is shot down, which gives a suitable wood-mat between ore and waste. As soon as the top floor has been shot down, slicing begins. The slices are taken about 10 ft. high (8 to 12 ft.). The work starts from one end of the stope and is carried backward. In the best practice small cross-cuts connecting the different raises are kept well ahead of the stoping. They are driven about 6 ft. high, leaving several feet of solid ground above. In stoping, the ore is taken out up to the mat of wood, which is held up by round stulls put in where required to secure the necessary working space. For these stulls rather thin, cheap timber is good enough. As the working face advances, or rather, retreats, the stulls are shot out, bringing down the mat with them, and new slices can then be started below. The top floor in the square-sets is not necessarily always at the same elevation, but conforms to the dip of the roof. The plan is to have at least one floor square-

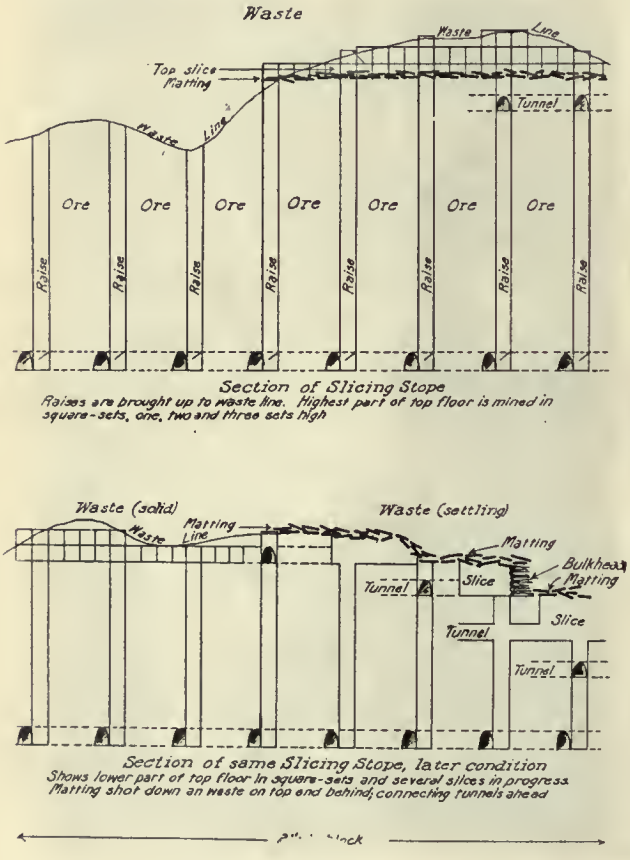

Fig. 6.

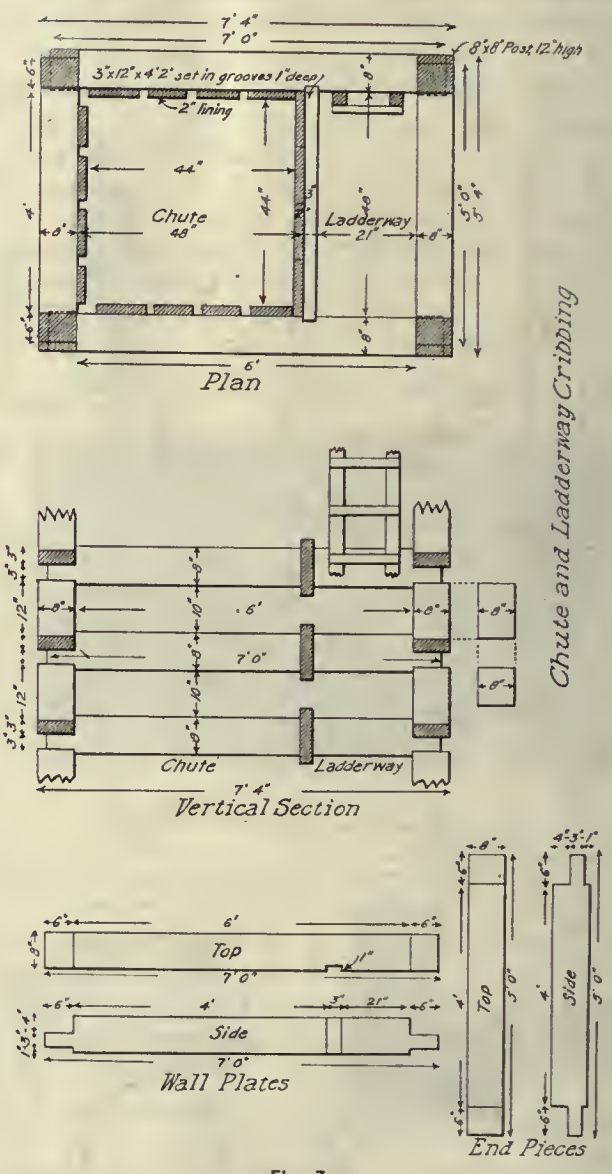

Fig. 7.

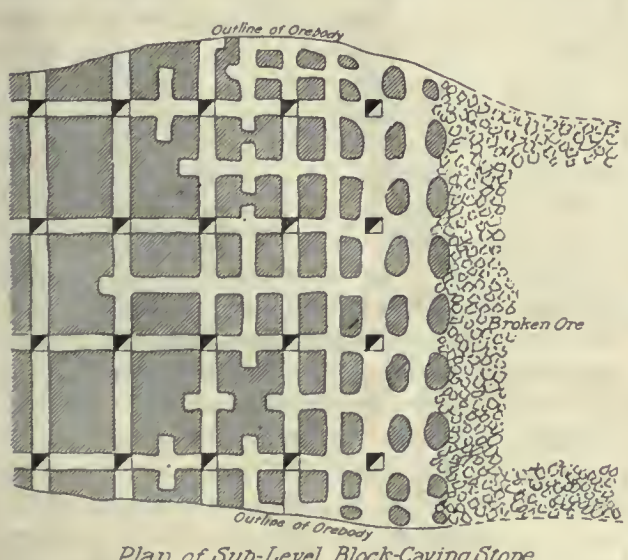
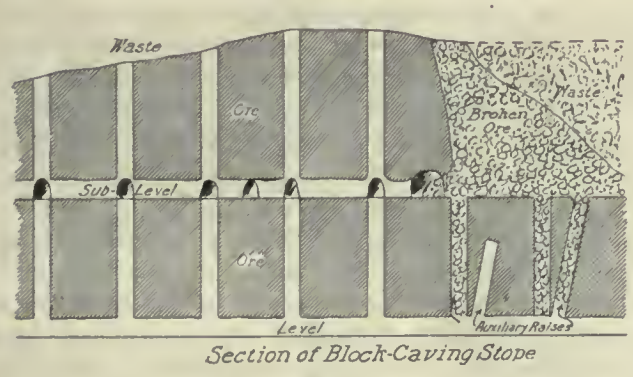
set all over the stope. Where the ore rises irregularly in smaller areas the ground is followed up, above the top floor, with square-sets also, so that locally there may be square-sets 4 and 5 sets high. If the ore widens out laterally at a lower level, these wide places are also first timbered by square-setting. For a while new floors were laid on each successive slicing floor, placing 8 by 8-in. timbers 8 ft. long one way, and 2 by 2-in. plank 10 ft. long, across them. This gave an excellent floor, easy to hold by means of the stulls of the next slice below, and there was possible some economy in stulls, but the timber cost increased materially and the system was abandoned for that previously described. Stulls should



Plan of Sub-Level, Block-Caving Stope



Section of Block-Caving Stope

Fig. 8.

not be set vertically, but with a slight inclination of the upper end toward the worked-out part, as the settling mat will soon push them back into vertical position. Fig. 6 illustrates the methods here described.

Raises are brought up for chutes and manways, or for chutes only. The standard raise is cribbed with 8 by 8-in. timber, 5 by 5 ft. for chute; 5 by 7 ft. for chute and ladder. The partition between ladder-way and chute is made of 3 by 12-in. plank 4 ft. 2 in. long, inserted on both ends in grooves 1 in. deep. The chute is lined with 2-in. plank placed vertically and fitted tightly on the side next the ladder, with open spaces on the three other sides. Chute space, after lining, is 44 by 44 in.; ladder space, 21 by 48 in. The cribbing is framed with horns 6 in. long and 3 in. thick, having tenons 1 in. deep on the upper and lower sides for the insertion of short 8 by 8-in. posts, 1 ft. long generally, but up to 2 ft. 4 in. long in hard ground, making the height of a crib-set 1 ft. 6 in., or 2 ft. 10 in., as the case may be. Details of these raises are shown in Fig. 7. The bottom sets are placed in square-set fashion, with 10 by 10-in. posts, 9 ft. 6 in. high, and 8 by 8-in. sills and caps. The chute front is also built of 8 by 8-in. timber. The chute doors are either of iron or of wood. The spouts are of the usual pattern made of 2-in. plank. The width of chute is about 2 ft. Immediately above the bottom set follows a similar short set, 3 ft. high in the clear, with round posts, so that the chute-door can be moved up to this point in case the original chute becomes too low, from settling when the stope 'takes weight.' The first crib-set is laid directly on top of this short set.

Block-caving.—Block-caving stopes are laid out in much the same way as slicing stopes, by drifts and cross-cuts on the level and raises to the top of the ore, but mining a top floor is unnecessary with square-sets. While a square-set top floor with tim-

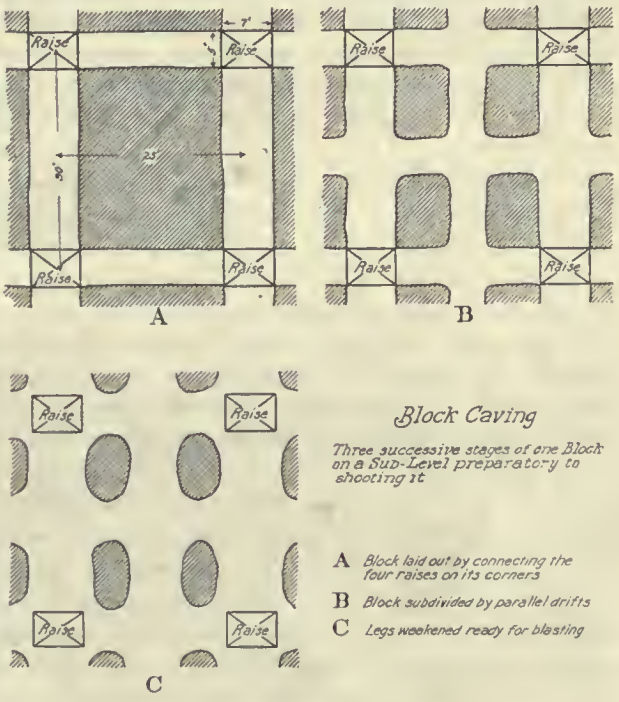


Fig. 9.

ber mat would temporarily afford a better separation between waste and ore, it soon is disarranged and the timber becomes a nuisance, blocking the chutes. It would not be necessary to push the raises to the top of the ore if the waste line could be established and maintained otherwise. If the raises are brought up to the waste, it is a good idea to strip them of timber before the actual caving begins. The operation is as follows. At a certain distance—20 to 35 ft. below the top of the ore—a working floor is started, called the 'sub,' or sub-level. The height of these sub-levels depends on the character of the ore. The easier and more regular the ore breaks, the higher are they taken. On them all raises are connected by drifts and cross-cuts, leaving blocks about 20 ft. square, in case of 5 by 7-ft. raises, 25 and 30 ft. between centres. These blocks are subdivided again

by other intermediate drifts and cross-cuts run parallel to the first series, leaving the block of ore standing on four legs. These are weakened by drilling and blasting as far as safety permits, and again drilled preparatory to the final blast, as are also the backs of all the drifts. This work is done with hammer-drills (Waugh, Shaw, and others). When a part of the stope has been prepared in this way the pillar and back holes are loaded and blasted electrically. The broken ore is shoveled into the chutes from that part of the stope still standing and drawn out below through the original chutes, and through others that are driven up to near the sub-level and then holed through into the broken mass of ore. The original raises are as a rule vertical and timbered. The secondary ones can be inclined, and if the ground is solid, may not require timbering. The ore is drawn out until mostly waste begins to show at the chute. Occasional blasting to break boulders will usually keep a chute going as long as needed. In principle, this method of stoping makes it possible to dispense entirely with timber, except in the original raises, where it can be recovered. In practice stulls will generally be found necessary here and there, but the less timber used, the better. Fig. 8 and 9 illustrate the method of working a block-caving stope.

Comparison Between the Different Methods.—Square-setting can be done under the best conditions prevailing at Morenci for about 80c. per ton of ore extracted, at least 20% of which would be for the timber alone; but unfavorable conditions, such as heavy ground, by necessitating reinforced timbering, careful filling, and small-sized stopes, make the cost run up to $2 and more per ton of ore. Slicing would cost, under favorable conditions, perhaps 60c. per ton. While requiring nearly the same amount of timber, it increases the tonnage mined per man and employs a greater proportion of common labor. Heavy ground will not affect its operation as readily as it does square-setting. One disadvantage is that first-class ore, from 6% copper up, used for direct smelting, can not be sorted out easily. An effort has been made to accumulate it in the stope and to run it out through one chute, set aside temporarily for this purpose, but the practice was abandoned. Leaving the leaner parts of the orebody, which can be done easily in square-setting, is also rather difficult and costly in slicing, as it breaks up the continuity of the mat and necessitates new square-setting below, should the orebody change again for the better. These difficulties make it necessary to mine the low-grade ore as well as the other. Block-caving can be done for about 40c. per ton. It gives the greatest tonnage per man and shift, and reduces the timber bill to almost nothing, but it is apt to result in mining large amounts of low-grade ore that would otherwise not be mined, and which, with the loss in concentrating, can not possibly pay expenses. Heavy ground affects this method but very little. Both slicing and block-caving represent a large initial expense, and take long preparation before a stope is ready for extraction, but after it is once started the production is more centralized and a very large tonnage can be rapidly mined from one stope by this method.

A careful sampling should follow closely the opening of a block of ground to be mined by the caving method, as mine samples as ordinarily taken prove usually to be higher than the ultimate mill sample covering the same block of ground, and in extraction, much of the profit of what should be won by cheap mining may be lost in taking too low a grade of ore. Sometimes more careful sampling might result in abandoning part of a stope already blocked out, as too low in grade to afford a profit, which otherwise might have been mined at a loss. To reap the full benefit of the cheaper working methods, improvements in mine sampling and concentrating are two important factors, and the Morenci companies, especially the D. C., have conducted researches in both branches for several years past. The floor plan of the stope on the different levels should be as simple as possible, and only enough drifts opened to afford the necessary facilities for tramming and starting the raises. The upkeep of the raises and tracks will run into a rather heavy repair bill in any event, and this should be kept to the lowest possible point consistent with the rapidity of working, and handling materials and ore. Morenci is somewhat handicapped in reaping the full benefit of the cheaper caving methods. In the first place, its orebodies lack the regularity and the even tenor of value of some other porphyry ore camps. Then, its orebodies are not intact, having been worked in their richer and more accessible parts by square-setting, and as a result, in places, there are some badly cut up pieces of ground which now remain to be worked by the new system. Last, but not least, mining in Morenci is not very speedy. The camp is somewhat conservative: hand-drilling is still the prevailing practice, machine-drills having been introduced only these last few years. More rapid mining would certainly reduce the cost, especially of slicing, and make possible the recovery of a good deal of timber that is now blasted and lost, at the same time that it would increase the tonnage output per man. The work is now frequently handicapped by the closing in of the mat due to settling and by the necessity of close stulling. New orebodies that afford the opportunity of close prospecting by boring present many advantages, as in these instances they might be mined by attacking the top by slicing, while raising and driving is going on below, thus minimizing the time required for keeping these workings open. Systematic boring, too, would give at the same time, a more reliable sampling than by any other method, even if it is liable to give a slightly higher average, as was pointed out recently by L. D. Ricketts at Cananea. Boring might also help to avoid losses in other ways. For example, at Morenci an orebody was prepared for block-caving, when another orebody was discovered in close proximity. By the time the second orebody was opened the ground of the entire vicinity was breaking and settling owing to the removal of the first. The drifts could not be kept open by reinforcing the timbers, even with use of angle braces or doubling. The raises were settling, and almost constant timber-changing and easing of ground had to be done.

United States Geological Survey

The fiscal year ended June 30, 1910, was one of great activity for the United States Geological Survey, as shown by the report of the Director, now in press.

The last annual report of this bureau directed particular attention to its accomplishment along conservation lines. It was stated that the specific contribution of the Survey to official conservation literature during the year was the coöpublication through the regular channels, advantage being taken of this opportunity to secure wide publicity for what in reality amounted to a progress report. The apparent trend of the day is distinctly toward the economic, so that now the annual statement of accomplishment ranges from work in pure science to work that has a strictly utilitarian bearing. To the public, interested in things that are practical, these two extremes may not appear to sustain any very intimate relation to each other. For instance, the studies of fossil shells and plants may seem to be of little practical use, yet they have proved of the greatest help in determining the coal horizons in the public coal-land areas and have directly contributed to the progress of the Survey's work in making rapidly a valuation and classification on the specific tonnage basis of the public coal lands in individual 40-acre tracts. Great progress in land-classification work during the year is shown by the report. Up to only a few years ago all Government coal land was sold at the minimum price fixed in the coal law, namely, $10 or $20 per acre, according to its proximity to railroads, without regard to its real value. Under the present regulations the value is fixed on the basis of tonnage and quality, and appraisals have run as high as $400 an acre and over. During the year 5,618,769 acres, classified as coal land, were valued and placed on the market at $380,955,646. New withdrawals of public coal lands for the purpose of classification and valuation, made principally in Montana, Wyoming, and in the newly discovered fields in Utah and Arizona, amounted during the year to 20,425,728 acres. The geologic field work is still over 7,000,000 acres ahead of the actual classification and valuation, and over 20,000,000 acres classified under former regulations yet remain to be reclassified on the basis of tonnage and quality. The passage, at the last session of Congress, of the law allowing agricultural entry of coal lands, such entry to carry only the surface rights, the coal rights being reserved to the Government, has resulted in the recommendation for withdrawal of extensive areas of lignite land in North and South Dakota.

In pursuance of the policy of securing the best use of the country's petroleum resources, large withdrawals of public oil-lands were made, pending legislation, in Arizona, California, Colorado, New Mexico, Utah, and Wyoming, aggregating 2,749,260 acres; but of these and former withdrawals 2,172,182 acres were restored to entry, geologic field examination showing them to be not valuable for oil. The total withdrawals at the close of the year were 4,547,121 acres. Great activity is shown in the withdrawal of lands, recommended by the Survey, in aid of proposed legislation touching the use and disposition of water-power sites; the total of such lands withdrawn during the year amounted to 1,219,818 acres, thousands of Western power sites being affected. The total outstanding power-site withdrawals at the close of the year were 1,454,499 acres. The need of a comprehensive oil-land law is discussed in detail by the Director. At present oil lands can only be entered under terms of the gold-placer law which is absurdly inadequate and tends to waste and even fraud.

The work of determining and classifying the phosphate deposits has been vigorously continued. As fast as discovered, public phosphate lands have been withdrawn from entry in the expectation of Federal legislation to remedy the defects in the existing conflicting mineral laws that are employed in acquiring these lands. The public-land States contain large deposits of phosphate rock, probably the largest in the world, and it is believed sound policy to keep the phosphates for American farmers. There is no intention of hindering development for domestic use.

The Bureau of Mines having been organized July 1, 1910, the Director of the Geological Survey takes occasion to review the work of the technologic branch, at that date transferred to the new Bureau. This work began at the Louisiana Purchase Exposition with an appropriation of $30,000 for analyzing and testing the coals and lignites of the United States under the direction of the Geological Survey. Later appropriations for fuel testing added to this appropriation $1,357,000. This branch of the Survey also expended $412,500 for the investigation of structural materials and $300,000 for investigations of mine accidents. On July 1 the fuel-testing and mine-accident work was transferred by act of Congress to the new Bureau of Mines, the structural material work going to the Bureau of Standards.

In Alaska a large amount of regular topographic and geologic work with reference to deposits of gold, coal, copper, etc., was accomplished, and a special comprehensive plan was formulated for making subdivisional land surveys in the agricultural sections of the territory. The topographic branch includes a large portion of the field service of the Geological Survey. During the year 36,539 sq. mi. in the United States proper were topographically surveyed in detail. The Survey has its own engraving plant. It is the greatest map-engraving establishment in the United States. The total number of maps and miscellaneous printing delivered during the year was over a million and a third, nearly three and a half million printings being required, as many of the geologic maps are in eight to ten colors. It is noted that over 600,000 of the topographic and geologic maps were distributed to the public—about five-sixths of which were cash sales—as well as more than half a million reports.

Clay Cutout, Isabel Dredge

By W. B. Winston

The ground of the Isabel Dredging Co., at Jenny Lind, Calaveras county, California, contains probably more loam and clay than any other at present being successfully dredged. The relative amounts of gravel and loam under various conditions are shown in the accompanying figure, 1. Under average condition, I, the material contains 10 ft. of loam, 10 ft. of clay, and 10 ft. of tight gravel; least frequently, IV, 28 ft. of loam and 2 ft. of loose gravel are present. The worst conditions as regards operation, are illustrated in Fig. II and III. In the case illustrated in II, 10 ft. of loam and 20 ft. of gravel, clay, and float bedrock are present, and in III, 6 ft. of loam, 22 ft. of clay, and 2 ft. of tight gravel. The largest percentage of gold is found in the tight gravel under conditions I and III.

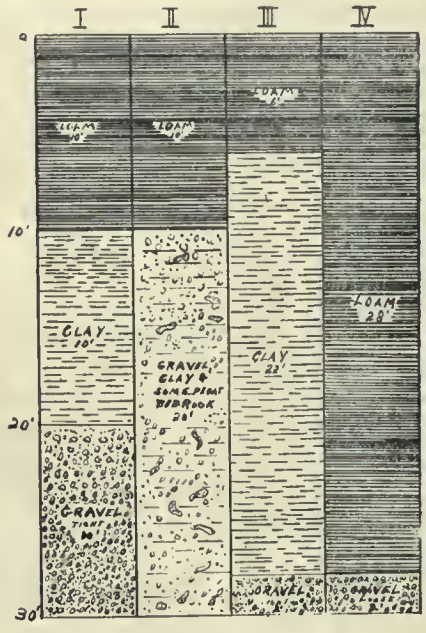

Fig. 1. Sections of Isabel Ground.

The Isabel dredge was originally equipped with side-flow tables and, in order to take care of the clay, with a combination revolving and shaking screen—this last arrangement was not a success and the former management experienced much difficulty in handling the large amount of clay, which, being stieky, is discharged with difficulty from buckets, and while going over the gold-saving tables forms balls which are apt to rob the riffles and probably

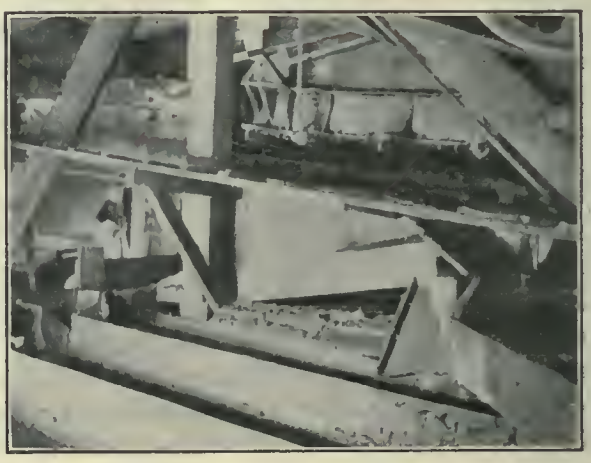

Fig. 3. Device for Enclosing Table Shown at B, and Clay Deflecting Plate at A, in Fig. 2. Part of Gold-Saving Tables in Foreground.

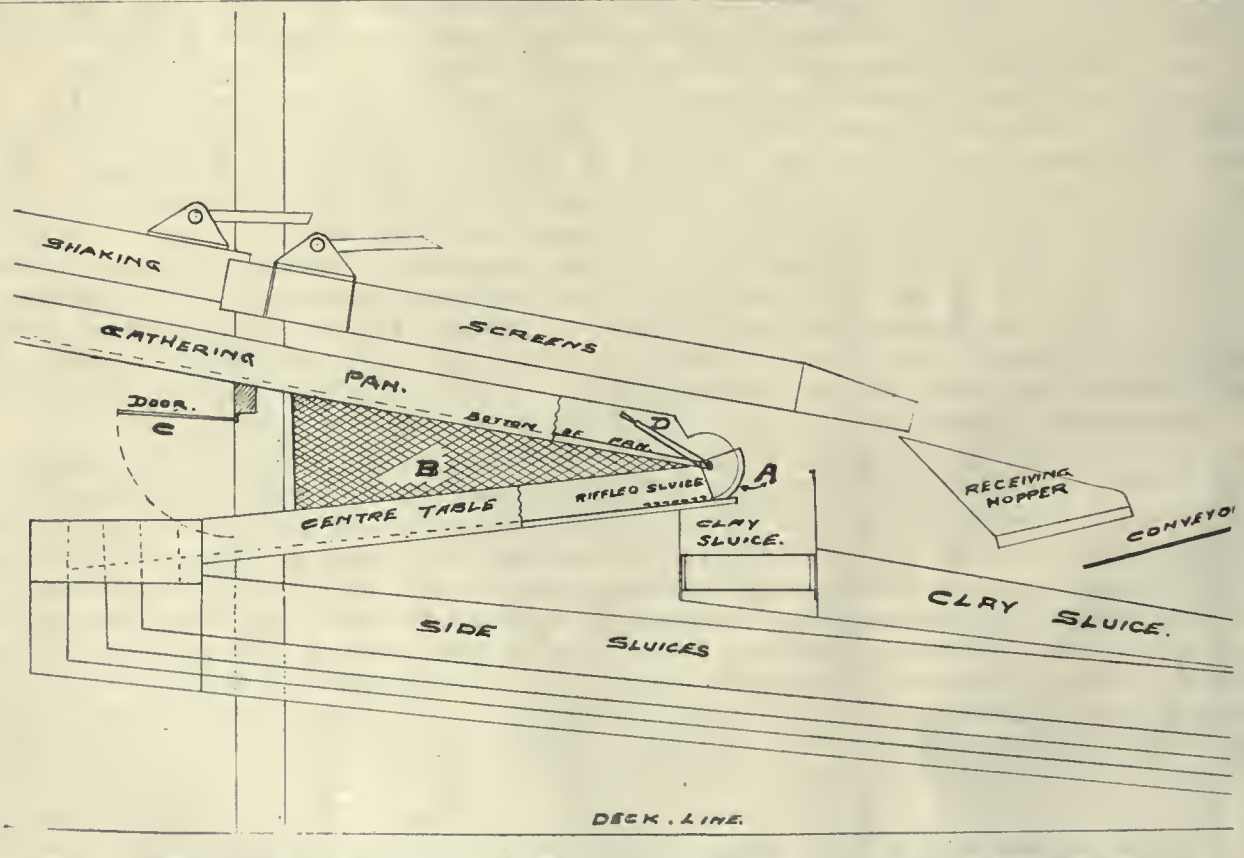

Fig. 2. Deflecting Plate for Cutting Out Clay, A, With Operating Handle, D; Screen for Enclosing Main Gold Table, B; Door for Locking Enclosed Table, C.

did cause considerable loss of gold. When, after the reorganization of the company in 1909, the dredge was partly remodeled and strengthened, the old gold-saving tables were replaced by the longitudinal Holmes type and a clay cutout, or deflecting plate, designed by Fred J. Estep, present resident manager, placed at the lower end of the pan under shaking-screens as shown in Fig. 2. This deflecting plate A, which is pivoted and operated by a lever D, is raised while digging in loam or clay, thus causing all material passing through shaking-screens

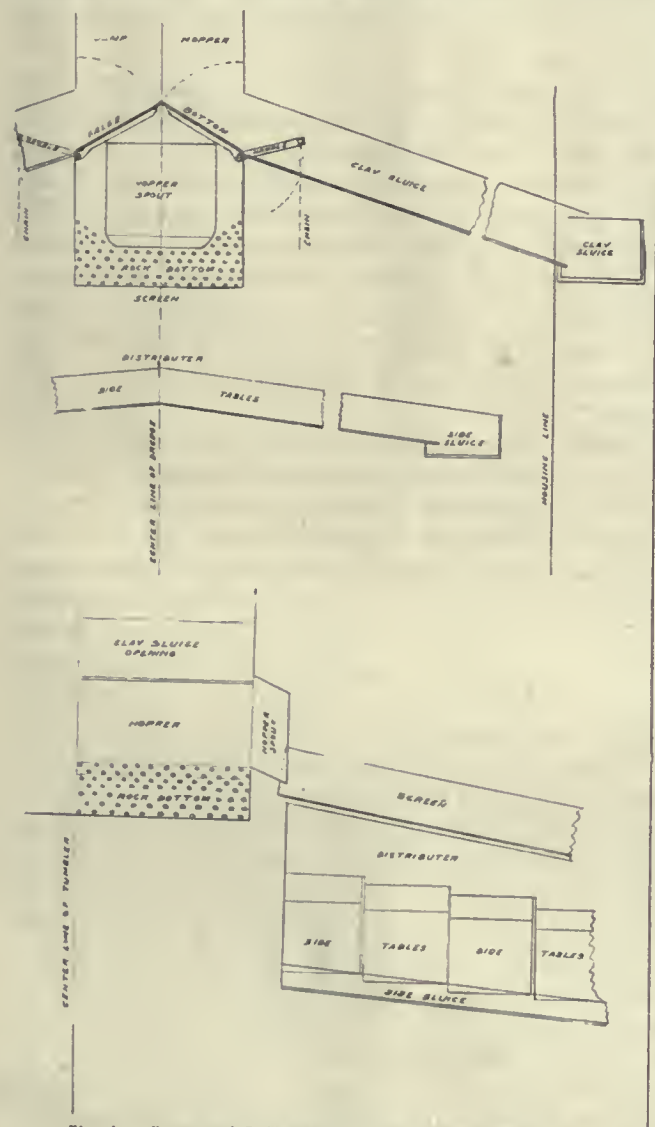

Fig. 4. Front and Side Views of Clay Cutout Device for Side-Flow Tables.

to flow into a separate sluice. The top of the clay sluice is directly under the deflecting-plate and runs over the gold tables on one side to end of the housing at the stern where it empties into a tail sluice which extends a considerable distance beyond the stern of dredge and the tail sluice from gold-saving tables. The large lumps of clay do not pass through the screens but are carried out over the stacker. While digging in gravel the deflecting-plate is let down in position, as shown in cut at A, thus causing all material from screens to pass over gold-tables as usual. This successful arrangement, together with properly arranged sprays in hopper, for loosening clay in buckets as they dump, has obviated practically all the delays and gold losses due to clay. At present the average amount handled per digging hour while in gravel is, for condition I, 110, for II, 150, and for condition III, 65 cubic yards.

A practical and simple arrangement to insure against theft of amalgam from tables was also installed by Mr. Estep; it consists of a wire netting B and a door C which together keep the principal part of the gold-saving tables under lock and key.

An arrangement of a clay cutout for use in conjunction with side-flow tables is shown in Fig. 4. It consists of a false-bottom placed above the hopper spout and made of two doors so arranged that by means of a lever and chain they can be raised and lowered in position, thus forming a false dump-bottom while down, and doors for apertures leading to clay sluices while up. As in this arrangement none of the material would pass over the tailing stacker, the two sluiceways, which could be carried a considerable distance beyond the stern of dredge, would probably prove advantageous.

LODES WITHIN PLACERS

A placer claim for which a patent has been issued is presumed to contain no vein or lode of value, the patent being issued upon the sworn statement of the applicant for patent, that to the best of his knowledge and belief no such vein exists. However, "a failure to disclose known lodes in the application (for patent) will not make the patent cover them, nor prevent the issuance of a subsequent lode patent." (South Star Lode, 20 Land Decisions; Dept. Int. 204.) By the express provisions of the statute such failure must be construed as a conclusive declaration that the claimant of the placer claim has no right of possession of the vein or lode claim. Moreover, a placer applicant will not be allowed to amend his application, so as to embrace therein veins or lodes discovered by others after the location of the placer claim, but prior to the application for the placer patent. Where, after a placer patent has issued, another person wants to apply for a patent to a lode in the placer as a 'known lode,' he must first get a departmental inquiry to establish that the lode was known to exist at the date of application for placer patent. For the reason that 'known lodes' are reserved and excepted from placer patents, the lode claimant does not have to adverse the placer patent. It is only where the lode patent is applied for first that adverse proceedings are absolutely required.

The prospector must learn to discard prejudice. Never mind how things looked in the old camp, try everything in the new. The most unpromising rock may be rich in gold or silver. Give attention to all heavy substances, regardless of color. Tungsten minerals are black or white; lead may be white or stained with iron oxide or copper carbonate; copper ores present many hues; barite may be mistaken for scheelite (calcium tungstate); calcium borate (colemanite) may be thought to be calcite and vice versa; silver sulphide often looks like worthless manganese or iron ore; and tin (cassiterite) may be mistaken for any one of several far less valuable minerals.

Mining Outlook in Western Australia

By A. Montgomery

*I doubt if there is any place in the world which offers the man anxious to get a small mine of his own a better chance than Western Australia, for there is any amount of ground open for prospecting, and in most of the older districts there are facilities for crushing the ore within reasonable distance. Cartage is easy almost anywhere, without having to spend much money in making and clearing roads. Many men, therefore, have made a good living at working mines for themselves, and many have made fortunes, without ever approaching the market. A prominent instance reeently is that of the Fenian mine at Meekatharra, owned by four men. It is opened to a depth of 625 ft., has its own battery, cyanide plant, and winding machinery, and when I left the State was putting up a new plant out of revenue. It has paid £77,000 in dividends, and the lucky owners were said to be getting dividends of £2000 per month. Few have been so successful as this, but many other working parties have done well. A great many are getting plants upon their mines and settling down to steady work, though often better organization and management than their own would make the mines far more profitable, the miners being often anything but good business men, and frequently indifferently skilled as miners. When a mine gets to the stage of being systematically worked, with aid of machinery, it is probably best in the majority of cases that it should be handled under a skilled mining man. There is nothing in the common reproach that the people of Western Australia are themselves inactive in opening up their mines, but another objeetion which is constantly being brought forward as a reason why the British investor should pass Australia by and put his money into foreign countries, namely, that the conditions of tenure of mining property are onerous and unsatisfactory in the former, will bear examination. When instances and specific complaints are asked, it is soon found that the statement is based on misconceptions and misunderstandings of the true position made by people who do not understand—and often appear not to want to understand—the facts of the case. It would take far too long now to make a comparison of the terms offered to investors in mining properties by the various countries which are inviting the aid of British and European capital, but when the matter is closely examined, any unbiased investigator soon finds that there are few, if any, countries (personally, I have not been able to find any) which give terms more favorable to the investor than Western Australia. The whole tendency of recent legislation has been to make them still more so, it being well recognized by all responsible political parties in the State that outside capital is required for active development of mining, and that good terms must be offered to attract it. Most of the complaints which have come within my own official knowledge have come from persons who have been trying to secure concessions and advantages to which they were not entitled, and who in many cases have been trying to evade performance of the obligations into which they entered when they undertook to work the mines. Such people often make a great outcry and present a fair-seeming *ex parte* case, but their statements should not be accepted until the other side has been heard. In 1907 and 1908 an investigation of the mining laws of Australia and New Zealand was carried out by a special commissioner, A. C. Veatch, sent from the United States Geological Survey at the instance of Mr. Roosevelt, at that time President, and who speaks very highly of the mining laws of the Commonwealth, and is especially complimentary to those of Western Australia. He strongly favors the leasehold tenure obtaining there rather than the freehold of the United States, and concludes by saying: "In short, viewed from the standpoint of present-day knowledge, the Western Australian mining law has proved a decided success."

Many of the objections urged against the mining laws of Australia arise from confusion of ideas as to the principles adopted by various countries. A person accustomed to freehold tenure is apt to misunderstand the laws of another country wherein, as in Australia, only a lease of mineral ground is granted, and the fee-simple is reserved to the State. There is much to be said for both principles of tenure, each having its own advantages and disadvantages, but, from the point of view of praetical mining business, there does not seem to be much to choose between them so long as a mine is in active operation. It is when a man wishes to hold ground locked up for speculative purposes, or sometimes for protection of previous expenditure, that the freehold becomes most desirable, but for all working purposes the matter usually, in practice, is one of indifference, there being rarely any difficulty under the leasehold system in obtaining all reasonable protection of any owners' interests. Objeetions are often raised to the powers left in the hands of the administrators of the mining laws to decide when concessions may be made to leaseholders in such matters as exemption from working their ground for a time, terms on which labor may be concentrated on one portion of a holding, and similar matters, it being complained that the investor is too much at the mercy of the Government of the day. There is little force in this argument. Most of the conditions governing such cases are, as far as possible, clearly prescribed by law, and, therefore, fixed and open to the knowledge of everybody, and where discretion is left to the administration, it is nearly always to meet the cases where special circumstances may require special treatment, and the decision cannot be made by rule. Such cases are inevitable, as in all other sorts of business. In dealing with people of one's own blood and language, a man can surely look for reasonable consideration of questions in which both sides are jointly interested, and just

*Abstract of paper read before the Colonial Section of the Royal Society of Arts, November 29, 1910.

treatment from local authority. Fears as to ultra-democratic legislation are on much the same footing; after all, the people in the colonies are much like those in the parent country, with similar notions of fair dealing and justice, and no more to be feared than their relatives in the United Kingdom. As a matter of fact, no Government of any party in any Australian State has ever yet refused to consider reasonable representations of investors and to meet them in a reasonable spirit.

When trying to find out lately what it was that the London market had against Western Australia, I was surprised to find that a great complaint was that the Government did nothing to encourage investors to go there, and was asked what we did to encourage any person to attempt to open mines in our State. In fact, a great deal has been done and is being done toward that end. First of all, exceptionally favorable terms are offered on which to acquire mining properties; British principles of law, justice, and procedure are followed in settling all disputes. If good propositions are offered, what more can anyone want than a fair chance of trying them, and a fair run for his money under the conditions which exist when he undertakes the venture? But the Western Australian Government is all the time improving these conditions, as far as it is able, by spending large sums annually in building railways, establishing mail and telegraph service, and other business facilities, providing water supplies, establishing State batteries, at which preliminary trials may be made, assisting in diamond-drilling, and even by direct monetary grants in some cases. The question is not what do they do to assist the investor, but what do they not do that is reasonable and feasible. The railway system comprised, to June 30, 1910, no less than 2145 miles of line, costing £11,384,000 for construction and equipment, and is being constantly extended. During 1907-8, 102 miles of new line were opened, the next year 101 miles, and last year 100 miles. Since last June the railway to Black Range has been opened, also one from Nannine to Meekatharra, and three others are expected to be opened before the end of June next. Others are projected, and on some of them work has been already begun, as in the case of the line from Port Hedland to Marble Bar, to open the Pilbara goldfield. These lately-undertaken railways are practically all for development purposes; they have not been built because it was profitable to do so, but in advance of settlement and development, in order to improve transportation so much that development could be greatly extended. Take, for example, the Port Hedland to Marble Bar railway. It would be idle to expect it to pay its way if the amount of work done in the district opened by it and the number of people in it were to remain as at present. But it is believed that the district is a good one and capable of great expansion of mining and population, if its present inaccessibility is overcome, and there has been little hesitation in authorizing the construction of the line once Parliament was convinced that this was the case. In the same way, agricultural railways are being run into nearly virgin country, to promote settlement. Of course, it is essential that, as far as possible, such work be made immediately productive to try to cover working expenses, and at least part of the interest bill, and while the volume of business is small, it is clear that somewhat high rates of freight may have to be charged. From time to time they are reduced as it becomes practicable to do so.

So also with the water supply. The great pipeline, 351 miles long, which supplies the Kalgoorlie mines with water from near the coast, has cost £3,236,232, and, though working expenses amount to only about 1s. 6d. per 1000 gal., including the whole system, interest and redemption bring the actual cost of the water sold last year to an average of 7s. 7d. per 1000 gal., and the full cost in the goldfields is estimated at 9s. 1½d. per 1000 gal. Water is sold to the mines at prices of from 4s. 9d. at Southern Cross to 8s. 6d. at Bulong per 1000 gal., where use is made of no other source of supply, the large mines at Kalgoorlie paying 7s. per 1000 gal., and a concession being made to poor mines by letting them have it at from 3s. 6d. to 5s. per 1000 gal. It is all very fine to grumble at the high rates of freight paid on some of the railways and the high cost of water, but surely the Government has conferred a great benefit in making these services available, even at these so-called high rates. They are far lower than those previously prevailing when there was no railway and no pipe-line. Plainly, the Government has given immense assistance to mining by its railways and water-supply expenditure, and while these services are not yet making profits which would be considered commercially satisfactory, and are in many cases hardly, if at all, paying actual working expenses, it is somewhat ungrateful and ungracious to demand still further concessions from the Government.

Besides the Coolgardie water scheme, there is large Government expenditure in making and maintaining wells and tanks throughout the State, and all the main roadways are now fairly well provided with water. Boring parties are at once sent to every new field which promises at all well, to try to find fresh water and battery-water supplies. The cost of established water stations during 1908, including interest and redemption, was £19,879, and the revenue was £12,634. The assistance given by the Government to mining in undertaking the water supplies is of incalculable value.

The assistance given by the State battery system does not appeal so much to an investor in public companies as to the man who is trying to open a mine by his own work. To such they have been an inestimable boon, enabling them to pay their way out of the ore. During 1909 there were 35 batteries in operation, containing 294 stamps capable of crushing 300,000 tons of ore per annum, but, as they were not kept fully employed, only 94,218 tons were actually crushed. Most of these batteries have cyanide plants for leaching the tailing, and some have been equipped with slime-treatment plant as well. From the inception of the system to the end of 1909 the State batteries have cost £275,320, and have

crushed 695,129 tons of gold ore, averaging a yield of 1.04 oz. of unrefined gold per ton, with a return of £2,658,966. They have also treated 449,492 tons of tailing (sand and slime) with a return of £42,192, bringing the total value of gold extracted to £2,701,-158. The ore treated is mostly in small lots, the batteries in 1909 treating, for example, 1741 separate lots, or an average of 54 tons per lot. From its inception to the end of 1909, the loss on the State battery system is stated as £105,411, or, including depreciation, £257,787. Though this is a large sum for the Government to have spent to assist in the opening up of the fields, it has, without doubt, been more remunerative than the figures would indicate, for the existence of the State mills has been the means of keeping many districts alive that would otherwise have been abandoned, and has so developed others—such as Black Range, Meekatharra, and others—that they have reached the stage when many of the mines have mills of their own, and some of them have been taken over by public companies.

Besides the State batteries, owned and worked directly by the Mines Department, there are many privately owned batteries throughout the State which receive subsidies from the Government to induce them to crush for the public. During 1909 there were 29 such batteries subsidized, which crushed 30,767 tons of ore. The average rate of subsidy was 1s. 5¼d. per ton, the rates varying greatly, according to locality. This represented direct assistance from the Treasury of £2207.

Under the Mining Development Act, loans, at a rate not exceeding £1 for £1 of their own expenditure, are made to those working mines to assist them in developing their mines and equipping them with machinery, the loans being repayable if the mine proves successful, and being secured by mortgages upon the mine and plant. Advances on similar but somewhat less stringent terms may also be made to persons putting up mills for public crushing purposes. Money may also be advanced on loan for boring with diamond and other drills, or may be expended by the Government on its own account, and subsidies are often granted to people who have to cart trial lots of ore long distances, and also to prospecting parties which are developing their mines below a depth of 100 ft. from the surface. Assistance is also given to prospectors in approved cases by providing them with Government camels, or horses and carts, to enable them to open up new country. The total expenditure for 1909 for these purposes was £13,896, and refunds were obtained to the amount of £2430. The principal and accrued interest on outstanding loans at the end of 1909 was £28,479, and £11,976 had been written off.

In conclusion, I wish to draw attention again to the exceptionally good opportunities offered by Western Australia to capital for legitimate mining operations, and also to men who have to depend on their own physical efforts to make their living, either in mining or in farming. There is a great field for enterprising and steady young men who would learn the business of prospecting and working small mines.

Gold Deposits of Japan

***History and Development.**—Many localities where placer gold could be found have been known from early times, but the majority of the quartz gold mines which are in working order now were first exploited during the seventeenth century. Since 1890, ten large mines have been opened, among which the three famous mines of Formosa and the largest deposits of Hasami are included. From 1875, the first year for which detailed records are available in Japan, the production of gold increased gradually until 1899. In that year the production rapidly increased owing to the discoveries of the placer gold of Yesashi in Hokkaido and the increase in the output from Formosa. During the five years, 1899 to 1903, the placer mining in Japan was the most prosperous, especially in the year 1901, when it reached the maximum, the placers yielding nearly 45% of the total production of gold. Since 1903 the output has not been so large, due principally to the sudden decline of the placer working, though there was always a certain steady increase of the quartz mine. According to the latest statistics the production of the placer mines is now only 4.8% of the total output of gold. The total gold output in 1908 amounted to 153,105 troy ounces, valued at £633,780, a little less than the value of the petroleum. Gold now occupies fourth place among the mineral products of Japan. About ten years ago, the prevailing method of extraction of gold from the ore was amalgamation. In 1900 the process of cyanidation was introduced at Hasami and in the next year at Ushio. The process made rapid progress, and at present there are few mines which do not use it. All-sliming is practised at a few mines. The smelting of cupriferous gold ores is gradually increasing the output of gold.

Kind of Ores.—Gold occurs chiefly in the native state, frequently mixed with pyrite, chalcopyrite, arsenopyrite, pyrrhotite, and stibnite. In rare cases it occurs in tellurides. The principal gangue mineral is quartz, often with calcite or barite. In many cases the ore is free milling, but sometimes is refractory. Few gold ores are absolutely free from silver, and vice versa, so that there is a transition between argentiferous gold ore and auriferous silver ore.

Deposits and Geology.—The mode of occurrence of the gold ores in Japan is as follows: (1) fissure-filling or veins: (2) impregnations; (3) metasomatic deposits; (4) contact-metamorphic deposits: (5) mechanical detrital deposits. Most of the gold in Japan is obtained from veins. There are two prominent types: (*a*) quartz veins in the pre-Tertiary rocks, and (*b*) quartz veins in the Tertiary rocks. In the former type the ore contains usually a smaller amount of metallic sulphides than that from veins in the Tertiary. Most of the mines are unprofitable owing to the smallness and the discontinuous character of the veins, and to the fact that the ores

*Abstract from 'Mining in Japan, Past and Present', published by Bureau of Mines, Dept. Agri. and Commerce of Japan.

are low grade. They are common in the sedimentary rocks of the Archean and Paleozoic, forming lenticular and bedded veins. In the latter, those in the Tertiary rocks, there are many famous gold mines. There are veins in both the sedimentary and eruptive rocks of the Tertiary age. The greater number of the mines which are now working in Japan belong to this type. In the impregnations many veinlets run irregularly and form a network of ore. This denotes undoubtedly the transition stage between veins and metasomatic deposits. There are two types of impregnations: (*a*) minute networks in granite, and (*b*) impregnations in the Tertiary tuff, shale, or liparite. The first class includes hairlike minute veinlets or ferruginous networks in granite. These networks seem to enter the spaces between each constituent mineral of the rock and even enter along the cleavage planes of feldspar and mica, so that when the granite is decomposed and becomes loose sand, the gold found therein is easily mistaken for an original constituent of the rock. The granite of the environs of Takahata mine in Riknzen is a typical example. The second type is illustrated in a large number of mines, especially in the dikes or bosses of liparite. Owing to the highly acidic and silicious character of the rock, the dikes themselves are frequently supposed to be large veins or masses of ore instead of impregnated rock. This type of deposit often accompanies copper. Porpets in Hokkaido and Washinosu in Rikuchu are the important mines of this type. The metasomatic deposits are formed usually just on or near the periphery of an eruptive rock or even in the eruptive rock itself. The deposit is often associated with copper ore as in the case of impregnations. Kinkwaseki in Formosa is a typical mine. Contact-metamorphic deposits occur occasionally in the contact zone between Paleozoic limestone and some eruptive rock such as granite. Strictly speaking, these are auriferous copper or auriferous iron deposits. Ota in Nagato and Rokuromi in Rikuchu are the examples. Detrital deposits have been worked since early times in the river beds or in terraces in the districts of Kesen, Wakuya, Hayakawa, Abekawa, Yoshinogawa, and elsewhere. Recently placers have begun to be worked in many localities in the Hokkaido and the river Kilung in Formosa. Up to the present time only the surface placers have received attention, and no gold dredging or underground working has been attempted. The largest nugget ever found in Japan weighed only 27.1 ounces, and was found in the gold-bearing gravel at Yesashi. The greater part of these deposits are in the Alluvium, while a few of them are discovered in the Diluvium. No Tertiary placers have been found. As a whole, the sedimentary and the eruptive rocks of the Tertiary age are the principal sources of gold in Japan. It is interesting to notice the fact that the greater part of this metal found in foreign countries comes, on the contrary, from quite a different source, namely, the rocks of the older formations.

Geographical Distribution. — Although gold is widely distributed, in small quantities, yet the chief gold-producing regions are comparatively restricted and are found in the three following regions: (1) the northern corner of Formosa; (2) several districts in Kyushu, especially in the province of Satsuma; and (3) the several districts of the northeastern part of Honshu, including the island of Sado. In Formosa there are three famous mines, namely, Kinkwaseki, Zuiho, and Botanko, which are being worked side by side in a small area of the district of Kilung. They are each, in fact, to be classed among the largest producers of gold in Japan. Almost the whole area of the province of Satsuma is ore bearing. There are many mines which have been worked from the most ancient times. The mines of Yamagano, Serigano, Ushio, Okuchi, and Kago are the most famous, but some of them now have doubtful futures. Among others in Kyushu, the most prominent mine is the Hasami, which is growing in production and undoubtedly, in a few years, will be one of the largest gold producers. In the island of Shikoku and the whole western part of Honshu there are scarcely any remarkable gold mines. In the provinces of Idzu, Kai, Hida, Noto, Kaga, and Tajima, there are small producers. In the northeastern part of Honshu many new deposits have been lately discovered, though most of them are not yet producing. The prospect here seems to be good. There are extensive deposits and impregnations in liparite or Tertiary tuff, although most of them are of low grade. In Hokkaido the prospecting has been insufficient and only a few occurrences are known. During the five years from 1899 to 1904 the placer workings in this province were exceedingly prosperous, especially after the discovery of the Yesashi, but that condition lasted for only a few years. In Sakhalin, there are a few localities where placer work was at one time carried on in the regions where Paleozoic formations outcrop. Work at all of these is at present suspended. All the important localities of gold deposits now worked are restricted to the inner side of the North and South Japan arc, with the two volcanic zones of Kirishima and Fuji. On the other hand, the outer side of the arcs, numerous veins which are not worked now, are in the pre-Tertiaries, together with resulting placers. This generalization coincides with the fact that in the inner side of the arc many neo-volcanic rocks, which are the chief sources of the deposits, are developed, while in the outer side they are rarely present.

The zinc-lead fields of Missouri, extending over into Kansas and Arkansas, are in what is termed the Ozark uplift, and make up one of the most extensive and valuable mineral regions in the world. Up to the present no intrusive rocks have been found associated with these ore deposits, or near them. These deposits are of the few anomolous occurrences of an abundance of ore with no apparent connection with eruptive rocks of any kind. The formation is limestone and chert and belongs to the Carboniferous. Below these rocks are Ordovician dolomites and sandstones for many hundred feet. The ore occurs in chimneys, pipes, and sheets. The mines are mostly operated by a system of leases.

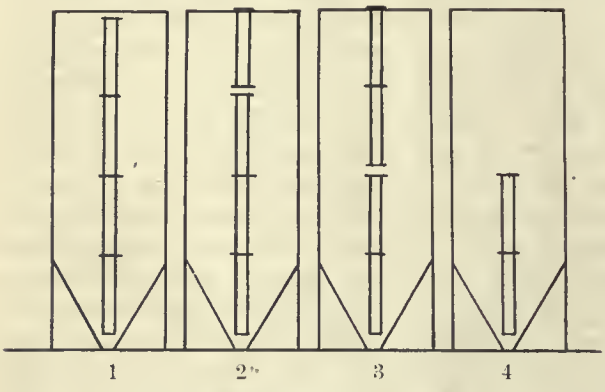
Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Modification of Pachuca-Tank Practice

The Editor:

Sir—In view of inquiries received for further details of the modified Pachuca-tank practice as carried out at the plant of the Zambona Development Co., which I described in your issue of October 22, I send the following: In all cases of cutting of the column pipes, the upper portion was first raised about eighteen inches, thus allowing most of the



1. Normal position of column pipe.
2. First alteration made.
3. Second alteration.
4. Final form adopted and used.

pulp to escape at the point cut, some of the pulp continuing to flow upward to the top and over the raised portion of the pipe. Noting the beneficial effects of the change, the raised portions of the pipes was removed entirely from all the tanks. The accompanying sketch, with explanations at foot, will, I think, make the whole operation clear.

AMOS J. YAEGER.

Minas Nuevas, Sonora, Mexico, November 15.

Metallic Sulphides in Alluvial Deposits

The Editor:

Sir—The interesting contribution by F. Lynwood Garrison on this subject calls to mind tests made on sand concentrated at one dredging property. These experiments were made during September 1909, in an endeavor to ascertain whether there was a loss in dredge tailing of sufficient importance to justify any attempt to save the gold so lost. The results obtained were as below. The sample called 'sand' consisted of material finer than ⅛ in. screened out from the tailing.

Sand.—The sluice material constituted 40% of the bank gravel. The sample of sand was 46% of the sluice material, and contained 15c. per cubic yard. Hence, 46% of 40%, which is equal to 18.4% of the bank gravel, at 15c. per cubic yard, represents $0.0276 per cubic yard, bank measurement. This sample was obtained when the dredge was digging in a rich streak; and if it be assumed, for the purpose of illustration only, that the rich streak was 3 ft. thick, it would then be necessary to divide the figure just given by 10 to get the amount per cubic yard, for the whole depth of bank, namely, $0.00276 per cubic yard. Under this view of the case, the loss is insignificant.

Black Sand.—The proportion of black sand contained in the sample of 46% of the sluice material, was determined and found to be 2.9%, and having a value of $1.79 per ton, or $2.68 per cubic yard of black sand. Hence, 2.9% of 46% of 40% = 0.53% of the bank gravel and 0.53% of $2.68 = $0.0142 per cubic yard of the bank gravel. But again, this black sand was obtained when the dredge was digging in a rich streak; and if, for the purpose of illustration, the same divisor be assumed as used in the case of the sand, it will represent but about $0.0014 per cubic yard for the whole mass of gravel handled by the dredge. No method is yet known by which these very small amounts of gold per cubic yard may be economically recovered. The black sand was tested by A. A. Hanks, who found that the gold therein contained may be recovered by cyanide, but it is a well established fact that the black sand itself cannot be separated from the tailing at a cost that will be covered by the value of its contained gold.

El Oro experiments indicated an extraction of from 97½ to 98% of the gold content of the bank. A Butte experiment showed 0.6c. per cubic yard of the sluice tailing; divide this by 2½ and there remains a loss of 0.24c. per cubic yard of bank gravel. While these data may not be perfect, they are, so far as I know, the best available on dredge recovery.

San Francisco, December 20.

Cyanidation of Concentrate

The Editor:

Sir—In your October 1 issue, 'Ingeniero KCN' asks for information about the treatment of unground concentrate. Sulphides direct from the vanners are being successfully treated here by percolation. Little headwater is used on the machines and about 50% coarse sand is allowed to come over with the concentrate. The material is dug out of the boxes and trammed directly to the vats. Lime is mixed with the charge, the amount varying from 6 to 9 lb. per ton of concentrate. Nothing is gained by giving water washes after addition of lime, as all ferrous salts dissolved will be re-precipitated as hydrates. The ore here contains a considerable amount of arsenopyrite, and a high alkalinity is maintained. About 0.50% titrating with deci-normal oxalic acid gives the best results. Pumping solution on the charge intermittently and allowing it to drain probably helps the extraction, but the method is slow. Blowing air up through the charge is more efficacious. Transferring from one vat to another is to be recommended where cheap labor is available. Excess of lime tends to form an incrustation in the pipes. The first solutions coming off will sometimes carry lime compounds in suspension, which, if allowed to run to the precipitation boxes soon coat

the zinc and prevent contact. I find that the only way to deal with these turbid solutions is to run them direct to the sumps, passing the zinc boxes, and pumping up again when adding strong cyanide to the stock tank. In the treatment of concentrate here the first solutions coming from a vat contain no free cyanide and carry little gold, hence they are run to waste. When necessary, water is added to the stock tanks to supply the deficiency. By this means the solutions are kept in good condition. The concentrate in question assays from $9 to $10 per ton and a 65% extraction is obtained. The ore is crushed through 15-mesh punched iron screens.

Kuk San Dong, Korea, November 17.

Avino Mines Company

The Editor:

Sir—My attention has been drawn to a letter published in your issue of November 5, over the signature of Ralph Nichols, formerly manager of the properties owned by this company. Mr. Nichols' statement to the effect that he suggested the shipment of a quantity of ore to Henry E. Wood, of Denver, for testing purposes is correct, but as there was no reason, at that time, to anticipate any improvement on the extraction obtained by water concentration in 1900, the directors did not feel warranted to act on Mr. Nichols' suggestion.

Some time after Mr. Nichols had severed his connection with the company, Mr. Wood advised the Avino board that he had perfected a new system of water concentration, which he felt sure could be applied to the Avino ores, and that high extraction would result. The directors then decided to ship a quantity of ore to Mr. Wood, and on receipt of his preliminary report instructed me to go to Denver to investigate the system and see further tests made. Mr. Nichols' statement to the effect that this company adopted Mr. Wood's recommendations without investigation is therefore incorrect. Mr. Nichols states that the "experimental plant was installed some two years ago, so that by now the company should be fairly out of the experimental stage." As a matter of fact, the erection of the experimental plant was not started until October of 1909, proving conclusively that Mr. Nichols has assumed to write on a subject of which he knows nothing. In Mr. Nichols' last report to the Avino Mines of Mexico, Ltd., he states that there was approximately 107,000 tons of ore, estimated as in sight, in the mine, and in his letter, under review, takes credit for having developed 100,000 tons of ore, in addition to several thousand tons of copper ore, which were shipped during the 'development' of these reserves. These remarks suggest the ridiculous assumption that there were no ore reserves in the mine at the time when Mr. Nichols took charge of the property, and do great injustice to the former management. There is another point to which reference should be made, that of capital. The Avino Mines of Mexico had about £30,000 available shortly after Mr. Nichols assumed the management, all of which was paid out during the 'development' of the 100,000 tons claimed. This is a large amount of money when compared with about £3500 with which operations were resumed in April 1909, after the mines had been closed for over a year. During Mr. Nichols' term of management copper sold up to 25c. per pound, and silver up to 65c. per ounce, as compared with 14c., the highest price for copper, and 56c. per ounce for silver since operations were last resumed.

Gabriel, Durango, Mexico, December 14.

Proposed New Mining Method

The Editor:

Sir—I have read with interest your editorial in the issue of November 26, commenting upon my article which discusses a proposed change in mining methods, and would like to add a few words to what has already been said. Without experimental data, a theoretical discussion of the possibilities loses much of its value, yet it may be useful in showing where the most serious obstacles are apt to be encountered. I do not agree with the editor that the most difficult part of the work in a channeling method would be in the breaking out of the blocks of rock between channels. When it is remembered that a man with a double-jack can often break up a rock as much as two feet thick, it does not seem a very difficult task for a machine a hundred times as powerful to perform the same operation. In quarrying, the object sought is to break out the blocks of rock in one piece: in mining it would be the object to break it into fragments suitable for handling. It is quite probable that in mining, rock would be found that could not be broken by channeling 20 in. apart, and that figure was only given for assumed average conditions. For more difficult conditions the channels would necessarily be cut at more frequent intervals, the same as in blasting, holes are drilled closer together and more dynamite used.

From a theoretical standpoint the possibilities of the proposed method resolve themselves into two phases: first, the mechanical, and second, the economical. The mechanical difficulties can only be overcome by actual trial and experiment. A discussion of the economic possibilities would be of interest, and I would like very much to see such a discussion by some one possessing the necessary data. In using dynamite the power required in the breaking of the rock is generated and used at the point where the work is to be done. In a channeling method the power would be generated on the surface of the mine and applied underground. Aside from the element of time, which depends solely upon the mechanical phase, the question seems to hinge largely upon the relative costs of the two methods of power generation and application. Dynamite has one great advantage, that of position within the rock, but possesses also a serious disadvantage in that the expenditure of energy can not be closely regulated. Data giving the relative cost of power generation from dynamite and from other sources would be of interest in this connection.

G. E. Wolcott.

Polaris, Arizona, December 10.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Very little tin is produced from stannite, the sulphide of tin, by far the greater part of the metal being obtained from cassiterite, which is found in commercial quantities in both veins and placers.

The flat-steel wire wrapped around the suction-hose of mine-pumps is not to prevent the water from bursting the hose, but to prevent its collapse from atmospheric pressure when the pump is in operation.

It is a wise miner who knows when to quit a mine that has once been profitable, but which is no longer so. Some mines have had several distinct periods of prosperity and adversity in their history—being much like men, in this respect.

Cross-cuts are an essential feature of proper mine development. Many a good vein or orebody has been missed by an otherwise competent miner by failure to cross-cut beyond the confines of the vein. Always drive cross-cuts systematically or you may overlook a fortune.

In cleaning boilers, allow the fire to die out and the pressure to run down to zero. Admit air on top, take off the plates and use the hose thoroughly, then clean out all remaining scale. Examine all available parts and have defects repaired. If grease gets into the boiler, use sal soda to neutralize it, and see that the grease is kept out thereafter. It is dangerous to have grease in a boiler, dangerous to the boiler and dangerous to your personal safety.

The standard flask of quicksilver contains 75 lb. The production of quicksilver has fallen off greatly throughout the world, but fortunately, perhaps, for all except the producers of the metal, the demand for quicksilver has been reduced correspondingly by the introduction of other methods of recovering gold and silver from their ores, including cyanidation, chlorination, various lixiviation processes, and a great improvement in and reduction of cost in smelting.

To line up a vertical shaft when sinking, four lines, one near each corner, are necessary for perfect alignment. It cannot be done by hanging a line at the centre of each wall-plate. The centres may be in direct line and true, but the shaft can easily assume the well-known 'corkscrew' condition when this method is used. For rough work an incline shaft may be kept in alignment by keeping the rope in the centre of the track. Even a slight deviation to one side or the other can be quickly detected.

Gash veins are superficial fissures which extend to comparatively shallow depths. They may be due to any one of a variety of causes, among them being the stretching, which occurs on the crest of an anticlinal fold; shrinkage in igneous rocks, and fracture due to earth movements. Some so-called gash veins are evidently only the lower part of a lens of quartz, the upper portion having been removed by erosion. This lens may be one of a series, extending both horizontally and vertically for a long distance.

The water in copper mines usually contains copper sulphate in solution, the amount of copper present varying somewhat, dependent upon the state of oxidation of the copper in the ore. At many mines it has been found profitable to pass the water, flowing or pumped from the mine, through a series of tanks or boxes containing scrap iron, and tin scrap, upon which metallic copper is precipitated from the solution. This cement copper, as it is called, contains about 60% copper, the balance being iron and earthy impurities.

A large mill is usually capable of more economical work than a small one, though there is a limit to this. For instance, the crew usually necessary to run a 10-stamp mill, can run a 20-stamp mill just as well. However, there are mills—5 stamps and less—where one man does everything on each shift. He looks after the plant supplying power; occasionally goes to the rock-breaker, attends the feeders, looks after amalgamation, and only on clean-up day does he have an assistant, when the night man stays on shift until that work is finished.

Seismographs are delicate instruments employed for the purpose of registering automatically earthquake shocks, both as to time, duration, and intensity; but no instrument made can foretell an earthquake, nor can the weather be relied upon as a means of predicting seismic disturbances, no matter of what character. The locus of a distant earthquake can be determined approximately by the length of duration of the tremors. It is only recently that scientific observers have been able to do this, and among the first to make use of this knowledge were Japanese scientists.

Spherical concretions sometimes observed occurring in sandstone are the result of an arrangement of the grains of sand about some nucleal body, usually a small quantity of organic matter, such as a piece of wood deposited with the sand. The sand in some strange way is arranged by nature in concentric layers about this centre, forming a globular mass of greater or less size. Near Los Angeles, California, concretions are known to occur up to 30 in. diam. In some instances these sand spheres contain a large percentage of iron oxide. They are then much harder than when the iron is absent, and the concentric structure is usually much more pronounced. On a stream tributary to the Missouri river in North Dakota, there are millions of these iron concretions scattered over the surface, the result of erosion of the sandstone in which they were formed. The stream is aptly named the Cannon Ball river. Concretions of copper ore are found in some rocks, particularly the Permian, which are formed in a similar manner. In that formation also occur fossil fish and other fauna turned by metasomatic process to an ore of copper and silver.

Special Correspondence

BULAWAYO, SOUTHERN RHODESIA

Mining in Southern Rhodesia. — Globe & Phoenix. — New Company Acquires Properties.—Bulawayo and Salisbury, Rivals.— Activity at Gatooma.

The repairs to the main shaft of the Globe & Phoenix mine have been completed and the company resumed mining and crushing a few days ago. Since the normal production is close to £30,000 per month, and the gold output of the whole of Southern Rhodesia in August was worth £191,423, it is evident that any unfavorable conditions at the Globe & Phoenix would affect the industry as a whole. The mine continues to be opened in satisfactory manner, the reef width and ore-values on the sixteenth and seventeenth levels being especially encouraging. This is the deepest mine in Southern Rhodesia, and the results obtained in the lowest workings are of the greatest importance to the company, and to the country, since it has been often alleged that Rhodesia is a territory of small rich quartz shoots. At the end of last year the company had 171,507 tons of ore in reserve, the gross value of which was estimated at £1,124,878, as compared with £485,020 at the end of 1908. It is understood that during the current year this tonnage has been largely added to and that the value of the ore in reserve

Typical Rhodesian Small Mine.

has been augmented.——Prominent among Johannesburg and London firms which recently have acquired interests in Rhodesia is the Consolidated Mines Selection Co., which has floated a subsidiary enterprise, styled the Rhodesia Mines Selection Co., to acquire and work properties in Matabeleland and Mashonaland. T. G. Hamilton, president of the Transvaal Chamber of Mines and managing director in South Africa for the Consolidated Mines Selection Co., recently visited Rhodesia, and selected Salisbury as the headquarters of the subsidiary company. Interests have been acquired in both Matabeleland and Mashonaland, the most important being the Arizona in the Twelo district and the Buller and Turkois in the Lomagundi district of northern Mashonaland. The managing director in Rhodesia for the Con. M. S. Co. is Lewis Evans, formerly general manager for the New Modderfontein company.——Opinions vary as to which is likely to be the premier town of Southern Rhodesia. At present Bulawayo and Salisbury are the principal rivals. It is largely a question as to which town can lay claim to the most important mining developments in its vicinity. Until recently Bulawayo had an advantage in this respect, but later the important discoveries made in the Abercorn and Enterprise goldfields, in the vicinity of Salisbury, have brought about a marked growth in population there. Salisbury, too, is the seat of the Government. Most of the important mining houses operating in Southern Rhodesia have their head offices in Bulawayo, and many new mines are being developed in the vicinity of the town. On the railway line between these two towns—the capitals of the Matabeleland and Mashonaland provinces respectively—lies a rapidly growing town which is likely to rival both Bulawayo and Salisbury in a few years. This is Gatooma, situated about 90 miles southwest of Salisbury. Three and a half years ago Gatooma was merely a railway siding, in the vicinity of which were a few prospectors at work. Now it has two hotels, stores, and banks, with the Eiffel goldfields distant about 4½ miles from the township, and has a population of 400 to 500 white people. There are some promising mining properties on the Eiffel gold-belt. The Cam & Motor, Ltd., and the Eileen Allanah, and Arizona are the most important of these. The Cam & Motor mines were floated by the London & Rhodesian Mining & Land Co., the Weil Bros., and Lewis & Marks, with a capital of half a million sterling. According to a report made by V. S. Allen, the value of the ore 'available' in the two mines is £680,000. The Eileen Allanah and Arizona claims are owned by the Willoughby's Consolidated company. Recent development work on these properties has been encouraging. In the Eileen Allanah mine the depth of the reef has been proved to be 280 ft.; and in the Arizona claims it has been cut at 50 ft. in No. 1 shaft, which is 170 ft. from the Eileen Allanah block. The reef has been intersected in the No. 2 shaft as well, which is 100 ft. distant from the No. 1 shaft. Two more shafts are being sunk to cut the reef, the width of which varies from 7 to 21 ft. It is stated that the ore-body has been proved along a strike of more than 600 ft. It is estimated that every 100-ft. level developed will result in the profit of £70,000 or £80,000. The mine is being opened rapidly, and a compressor plant is to be installed.

LONDON

The Consolidated Gold Fields.—Production of Main Reef West.—Tin Deposits.—Lena Goldfields Company.

The yearly statement of the Consolidated Gold Fields of South Africa is always looked forward to with great interest, as it is a typical example of a promoting, or parent company originally formed to develop properties on the Rand, and more recently expanded as to its sphere of operations. It is also notable because it was the company identified with Cecil Rhodes' connection with the Rand. The Simmer & Jack was the property acquired on the outcrop to the east of Johannesburg and it has proved to be one of the most important producers in this goldfield. Subsequently deep levels in the vicinity were acquired, among which Simmer Deep, Simmer East, Knights Deep, and Jupiter are the most important. The company also acquired and developed the Robinson Deep, farther to the west, and holds much of the property adjoining to the south of Robinson Deep, notably the Turffontein. The report of the company for the year ended June 30 shows a profit of £993,381, as compared with £1,283,851 a year ago. The policy of writing down the assets to keep pace with the exhaustion of the mines is being continued, but, whereas £500,000 was devoted to this purpose a year ago, the sum of £200,000 is sufficient for that purpose this year. Dividends at the rate of 6% have been paid on £1,250,000 preference shares and 35% on the £2,000,000 ordinary shares. During the year the debentures have been reduced by £25,000 and now stand at £250,000. The reserve fund remains the same as before, namely, £2,000,000, of which one-half is used in the business of the company and one-half in government securities. The chief income of the company is derived from dividend-paying mines on the Rand, of which those already mentioned are the most important. The company also has a large interest in City Deep, which will be producing within the next few months. The list of other investments published in the report is, as usual, of great interest. The Shamva and other Rhodesian companies, and the Fanti, Wassaw, and other West Africans, account for large sums of money. The company has substantial holdings in the Victoria Falls & Transvaal Power Co., the Lena Goldfields, Oroville Dredging, Natomas Consolidated, and many other companies operating in various parts of the world. One investment representing about £50,000 is in the Northern Light Power & Coal

Co., operating in the Yukon district, of which little is heard, though its headquarters are in London. The report states that the mining operations on the Rand under the control of the company have been greatly hampered by the scarcity of native labor, and in Rhodesia and West Africa the same trouble is predominant.

The development of the Main Reef West property in the near western Rand, belonging to the Neumann group, is of special interest at present. This part of the Rand has not been as successful as others, and the success of this new deep level is therefore of some importance, especially as it adjoins the Bantjes, the new property about which so many injurious prognostications have been made. Operations were started at Main Reef West in May 1909, with 80 stamps, and an additional 40 have since been erected. Two tube-mills have been erected and another has been ordered, but none has been put in operation, as the amount of ore mined has not yet overtaken the capacity of the 120 stamps, which can comminute the whole of the present output to 30 mesh. The development and further equipment of the mine are progressing rapidly, and some quick shaft-sinking has been done. It is expected that it will be possible to greatly increase the output in about a year's time. During the year ended June 30 an average of 103 stamps treated 189,649 tons, yielding by amalgamation 46,387 oz., and by cyanide 27,104 oz., a total of 73,491 oz. gold, valued at £307,787. The yield was 7¾ dwt., or 32s. 5d. per ton, and the extraction was 92%. The working cost was £169,837, leaving a profit of £137,950, the figures per ton being 17s. 11d. and 14s. 6d. respectively. The company has been able to declare its first dividends, No. 1 and 2, amounting in all to £112,500, which is at the rate of 25%. During the year additional capital expenditure has been incurred, chiefly in connection with shaft-sinking and equipment, to the amount of £86,686, of which £5648 has been provided out of revenue, and the remainder out of the proceeds of an issue of £300,000 debentures, specially made two years ago for this purpose. The reports by the engineers show that progress is continuous and that the ore reserve is 74,000 tons higher than a year ago, standing now at 430,000 tons, averaging 7.9 dwt. The outlook is therefore highly encouraging.

The tin deposits in South Africa are gradually assuming an important position. Many of the more prosperous companies are operating gravel properties, and their concentrates bring high prices in England. Others which are developing vein mines have found unexpected difficulties in recovering the tin oxide. One of these is the Rooiberg company, which was formed in May 1908 to acquire mines in the Rustenburg district, Transvaal, situated in the northern slope of the Rooiberg range of hills, 40 miles west of Warmbaths station, and 70 miles north by west of Pretoria. The original promoters, the Oceana Consolidated, were not successful with this property, and the control is now with the Anglo-French-Farrar group. During the year ended June 30 the 10-stamp mill crushed 15,713 tons and produced 622 long tons of tin concentrate having an average content of 68.3%. The extraction was only 62%, and the middling, tailing, and slime have been saved for further treatment. The new consulting engineer, Edward J. Way, requisitioned the services of Amos Treloar, who did much good work at the dressing works at East Pool, Cornwall. Between them they are designing a modified plant with the object of effecting a greater saving. The developments at the mine are in the meantime proving satisfactory and the reserve on June 30 was 24,300 tons, averaging nearly 5% metallic tin. The receipts from the sale of concentrate were £56,135, and the working profit was £12,681. In order to provide for the new plant the capital of the company has been raised from £150,000 to £180,000 by the issue of 30,000 new shares which were sold at 30 shillings.

Lena Goldfields company was formed in 1908 to acquire the control of a Russian company, the Lenskoie, which has worked for many years alluvial gold deposits in valleys adjoining the Vitim river, a tributary of the Lena. Bodaibo is the town on the Vitim, being the centre of operations. It is at the mouth of the river of the same name. The flotation in London was in the hands of the Venture Corporation and the Consolidated Gold Fields of South Africa, for whom C. M. Rolker reported on the properties. The total share capital is 1,122,216 in £1 shares, of which 753,838 was purchase price and 368,378 was subscribed in cash for working capital, the total amount received being £401,815. The holding in Lenskoie shares represents 71½% of the total. The revised figures for the profit of the Lenskoie for the year, October 1908 to October 1909, were £519,455, as against £400,000 estimated. For the year October 1909-10 the extraction as reported by C. M. Rolker was about £1,600,000, and the managing director, Baron Alfred de Gunsburg, estimates the profit for the year at £600,000. The Lena Goldfields has just published a statement for the 15 months ended September 30 which shows a profit of £262,386, chiefly derived from the profits of the Lenskoie for the years 1907 to 1909. The only dividend so far distributed was one of 10% paid on November 25 last year, absorbing £112,221, and the directors now recommend the payment of another dividend of the same amount on December 22. During the year additional property has been acquired from the Industrial company, and property has been leased from the State Bank.

GOLDFIELD, NEVADA

The Consolidated Company's New Storage Batteries. — Development of High-Grade Ore.

During last week the newly installed storage battery and power equalizing plant of the Goldfield Consolidated Mines Co. was given its first practical emergency test, with results that were satisfactory and which demonstrated beyond question the value of the plant as a factor for economy in operation. For nearly nine hours the power supply from the main line between this district and Bishop creek, California, was cut off while the transformers at Alkali Springs, twelve miles west of Goldfield, were being moved from the old building to a new steel and concrete structure. From this point a northern branch of the line diverges to Tonopah. In the past when the power supply from the main line was interrupted all operation of machinery in the mines and mills was suspended, but with the aid of the new plant the Consolidated company was enabled to continue the operation of hoisting machinery, raising and lowering the miners, although no ore was handled by the hoists during this time. All the electric lights in mines, mill, and other buildings were kept burning, pumps were operated without interruption, as were also most of the machine-drills and compressors, and the mill continued working, though at reduced capacity. The storage bins at the mill have a capacity of 2000 tons and always contain at least a day's run as a precaution against shortage from any cause. The new electric plant is the outcome of exhaustive experiments conducted during the past two years by L. T. Merwin, the company's chief electrical engineer, who has visited and studied a large number of electrical plants throughout the country. By means of this system the stored energy is drawn upon at the moment of starting hoisting and other machinery, when the dial indicators register the 'peak' load, thereby maintaining greater uniformity in power used, minimizing the peak load, and resulting in a material saving in cost of power. All new buildings that have been in process of construction for several months are nearly completed, including the enlarged and improved refinery, and from this time forward this item of expense will be small. J. R. Finlay, the manager, has returned from New York, where he went to attend the quarterly meeting of directors, and it is expected that the report for the month of November will contain interesting information regarding the latest developments in the mines. From the 1000-ft. level of the Clermont a raise is being driven in the orebody exposed some time ago, and the result of this work has demonstrated the magnitude of the deposit at this depth, by showing the continuity of the seams of high-grade ore accompanying that of milling

grade. This vein is said to have maintained an average of $65 per ton. This ore-shoot will be opened soon on the 900-ft. level, and there is a considerable tonnage of high-grade ore exposed on the 750-ft. level of the Clermont, shipments of which can be made to smelters at any time it is desired to supplement the bullion production of the mill.

SALT LAKE, UTAH

Utah Copper's Dividend.—Park City Merger not Probable.—The Tintic Mines.—Water in Columbus Con.—The Rexall.

The Utah Copper Co. has posted its fourth quarterly dividend, amounting to 75c. per share, a total of $1,168,800. A rough estimate of the production of Utah Copper for the year is 89,000,000 lb., with profits of $3.50 per share.——The merger of Park City mines, in which it was expected that the Daly West would form the nucleus around which would be the Ontario, Daly, Daly-Judge, Thompson Con., and some smaller ones, seems to have come to a standstill. It was admitted by those interested that such a merger was being planned, and the preliminary steps passed off in such a manner as to make it appear that successful culmination was only a matter of time. The matter is resting at present, and it is probable that the plans never will mature.——

Utah.

In the Tintic district the Yankee Con. has levied assessment No. 4 of 2c. per share. The amount thus raised will be used to pay for the completion of a contract to sink the shaft 400 ft., and the contract price for sinking another 400 ft. Uncle Sam has declared a dividend of 5c. Iron Blossom, with $60,000 in its treasury, passed its usual dividend at the annual meeting at which the old board of directors was re-elected. Current report is that the company is undecided whether to declare a dividend or use the money to build a mill for concentrating the low-grade ore. The Opex has levied an assessment, and the Colorado has declared its usual quarterly dividend, this time 6c. per share, amounting to $60,000, bringing the total up to $2,300,000.

Two lessees working on a ten-acre fraction wedged in between the King David, Peacock Copper, and Cupric, in the Frisco district, opened a vein of rich lead ore at the surface. The claim, on being explored, showed three distinct fissure veins, and a 10 by 12-ft. pit sunk 15 ft., was all of the way in ore. An interesting feature of this item is that the fraction formely belonged to the King David, and when this portion of the ground was surveyed the fraction was left out as being of no consequence.——At the Columbus Consolidated there is a surfeit of water in the 400-ft. shaft from the main adit. Two more pumps have been ordered, and when these are installed the water can be controlled. The Columbus Con. probably has spent enough money in pumps and pumping to have paid for driving a drain tunnel which would have permanently unwatered the mine.——The Rexall company in Big Cottonwood has let a contract for the extension of its adit another 100 ft., and it is calculated that the main fissure will be cut in that distance. In driving this adit a minor fissure containing iron carbonate has been intersected.——The settling price for lead on the local market has been advanced from $4.40 to $4.50. This advance in price means an addition of $120,000 to the annual output of the State.

BUTTE, MONTANA

Moulton Mine to be Re-Opened. — High-Grade Ore From the West Colusa.—November Copper Output.

With the assistance of the Anaconda company, W. A. Clark promises to revive silver mining in this district through the re-opening of the Moulton mine, a silver property which has not been in operation for a dozen years. The Washoe smelter of the Anaconda company is now in a position to treat silver ore to advantage, and has given Mr. Clark favorable terms. It will be some time before the actual work of mining begins. After an idleness of 12 years considerable work in the shaft will have to be done. This is now in progress. The Moulton is 800 ft. deep, and in years past was one of the best silver producers in the West.——The West Colusa mine of the Boston & Montana company is shipping high-grade ore to the Washoe smelter. It is said that the ore is some of the richest ever hoisted out of a Butte property. Generally all the ore taken from the original Boston & Montana properties is sent to the Great Falls smelter.——The petition of the minority holders of Parrot company stock for an appraisement of the property of the company, has again been continued, this time to January 9. The attorneys for the Anaconda company and the Boston minority holders of the stock were both agreeable to the further postponement. There is a belief that arrangements may yet be made whereby the Parrot petitioners will come to the conclusion that the holders of Parrot stock got a very fair deal when the majority decided to sell to the Anaconda company.——F. A. Heinze has lost one of his ablest and most capable men in Montana, December 1, through the retirement of Charles R. Leonard from all connection with the business of Mr. Heinze. For several years Mr. Leonard was at the head of the Heinze legal affairs in this city and was the leading spirit in the organization of the Davis-Daly Copper Mining Co.——The November output of the mines of the district amounts to 22,900,000 lb. of copper, of which the Washoe smelter at Anaconda turned out 16,000,000 lb., the Great Falls smelter 5,900,000, and the East Butte smelter 1,000,000. In the 16,000,000 lb. from the Washoe smelter is included 500,000 lb. of copper belonging to the Tuolumne company and nearly 2,000,000 from the North Butte mine, while in the Washoe returns there was some ore from the West Colusa of the Boston & Montana group. As compared with October, the returns show an increase of 100,000 lb. from the Washoe smelter, and a decline of 300,000 from the Great Falls smelter. The decline in the Great Falls return is due to the fact that some of the ore usually going there was sent to the Washoe in Anaconda, and to the further fact that more low-grade ore was shipped to Great Falls in November than in October.——The Elm Orlu is shipping nine cars per day, five being zinc and four copper, and the Poser is sending three cars per day to the Washoe smelter. The zinc ore is being treated at the Clark concentrator at the Butte Reduction Works.——Some time ago the Butte & London Development Co. held a special meeting of the stockholders to consider the raising of $10,000 to assist in paying off a judgment for personal injuries, amounting to something like $17,000. The meeting did not take kindly to the mortgaging of the property, so now the machinery of the company is being advertised for sale, which is taken to mean that the directors will not operate the property for

some time to come.——A hoist has been installed in the 1200-ft. station of the Tuolumne mine, and sinking the shaft from the 1400-ft. level to 2000 ft. has been commenced. This will not interfere with the regular hoisting of ore. ——The stockholders of the Butte & Superior company are still waiting for official information on the financial condition of the property. There are reports that a large portion of the bond issue remains unsold and that the management is unwilling to have the bonds fall into possession of outsiders, although it is stated that there are financial interests willing to take $500,000 worth of the securities on the same terms as they have been offered to stockholders.——The Butte Central Copper Co., operating the Ophir mine, is to build a concentrator. An unsuccessful effort was made to have the ore treated at the smelters, hence the decision to erect the mill. Freeman Davison, the organizer of the Butte Central Copper Co., has been in the city making an examination of the property and arranging for further improvements and the development of the Ophir mine. Miners on the 500-ft. level are blocking out ore, while a crew is sinking the shaft to 1000 feet.

WASHINGTON, D. C.

Projected Oil Land Legislation.—Alaskan Mining Claims.—Test Coal Land Case.—Patash Controversy.

With the opening of the session of Congress last Monday came a batch of mining bills, the most important of which is that introduced by Reed Smoot, Senator from Utah, which provides for the granting by the Secretary of the Interior of permits to explore and prospect for oil and gas on unappropriated and withdrawn lands. One provision of the measure is that the lands covered by a permit shall be in a compact body, not over four miles in length and not to exceed 1280 acres, and no more than one permit shall be held by any person, association, or corporation. The applicant shall pay five cents per acre for the right to explore and prospect.——Knute Nelson, Senator from Minnesota, and chairman of the Senate Committee on Public Lands, has introduced by request a bill regarding mining claims in the District of Alaska. Briefly, it provides that no person shall locate an area of more than two full-sized claims, whether they be placer or lode claims. A placer claim shall not exceed twenty acres in area, and a lode claim not more than twenty and sixty-six one-hundredths acres; that all mining claims hereafter located shall be rectangular in form unless prevented from so being by the lines of previously located claims; and placer claims shall not exceed 660 ft. in width, or 1320 ft. in length for each claim; nor shall lode claims exceed 600 ft. in width, or 1500 ft. in length; that the location of association placer mining claims and the extralateral rights to vein or lode claims as provided for in the statutes be hereby abolished as to the District of Alaska.——Weldon B. Heyburn, Senator from Idaho, introduced a bill to exempt owners of unpatented mining claims from performing annual labor upon such claims for the year 1910 by reason of the losses suffered by these owners by forest fires.———Donald A. McKenzie, of Alaska, was arrested in this city, December 8, on a requisition from the United States authorities at Spokane, Washington, in connection with alleged land frauds in Alaska. Mr. McKenzie was released on bond by a United States Commissioner. The allegation in the indictment is that McKenzie, with four others, conspired to fraudulently procure title to about 2000 acres of coal land in the Katalla district, Alaska. The Government's contention is that a coal locator may not lawfully enter into an agreement prior to completion of entry to sell his claim, and that no other person may lawfully enter into an agreement to buy his claim prior to its completion. It is understood that it is practically a test case of the Government's position in regard to coal lands in Alaska.——Prominent lawyers from Philadelphia, New York, and Baltimore have been urging Philander C. Knox, Secretary of State, and John B. Osborne, chief of the Bureau of Trade Relations, to adopt a vigorous policy toward Germany in connection with the refusal of that government to permit the execution of the contract which Americans hold for the delivery of potash from German mines.——The United States mints during the month of October coined more than $14,000,000, of which more than $13,000,000 was in gold.

ALPINE, TEXAS

The West Texas Mining Congress Organized to Formulate Changes in State Mining Law.

The movement of mining men and others to bring about the enactment of a new mining law which will encourage prospecting upon lands owned by the State of Texas, and protect the owners of mining claims, took definite shape at a recent meeting of the West Texas Mining Congress held here. The special object was to discuss the matter of proposed mining legislation and to memorialize the legislature, which is due to convene in January, to repeal the existing mining law because of its obnoxious and unsatisfactory provisions. More than fifty representative mining men from different parts of western Texas were in attendance. The meeting marked the inauguration of the West Texas Mining Congress, of which J. D. Jackson, of Alpine, was elected president, H. C. Phillips, vice-president, and W. J. Yates, secretary. After a general discussion, resolutions were submitted and adopted voicing the sense of the meeting. These resolutions approve a portion of the mining law that

Terminal of Del Carmen Mining Co. Tram in West Texas.

was passed by the last legislature, but which was vetoed by Governor Campbell because it contained an unconstitutional provision relating to the State's control of minerals upon islands along the Gulf Coast. The Congress held here recommends that this unconstitutional provision be omitted from the new bill, and that the following changes and additions be embraced in the same:

"1. That a uniform price be placed upon all mineral lands, as follows: For lands containing precious minerals, $15 per acre; for lands containing the baser minerals, $10 per acre, provided such lands are situated within five miles of a railroad; and $5 per acre for land more than five miles from a railroad.

"2. That an appropriation be made for the purpose of carrying on the work of the mineral survey in western Texas, which was discontinued in 1905; that said appropriation is to be for a study of the geology and the mineral resources of Texas.

"3. That this Congress is opposed to any plan whereby

the owners of mineral lands would be required to pay any royalty to the State of Texas upon minerals mined from the lands so disposed of."

J. T. Robison, State Land Commissioner, is an advocate of the proposed mining law containing a provision by which a stipulated royalty shall be paid the State on all ore extracted from mines situated upon State lands. If he does not recede from his position on this question it it probable that it will be the chief subject of contention when the matter of enacting the new law comes before the legislature. The State of Texas owns several million acres of land in the Western part of the State, on some of which rich minerals are known to exist, but owing to the lack of an adequate mining law very little has been done toward the development of these resources. Under the present law the State Land Commissioner has absolute authority to fix whatever price upon the land that he may see fit after the mining claim has been brought to a producing stage. No one cares to develop a claim in the face of the uncertainty as to the price he may have to pay the State for the property.

NEW YORK

Second Conference of Copper Men. — A More Effective Curtailment Desired.—Lake Superior Mines.—Boston & Montana.—Comment on Western Mines.

There was another banquet at Sherry's this week for the copper producers. The initial 'spread' was given by John D. Ryan; on this second occasion, Eugene Meyer, Jr., was the host. Among Mr. Meyer's guests were George W. Perkins, John D. Ryan, Daniel Guggenheim, Solomon Guggenheim, Murry Guggenheim, W. C. Paine, W. B. Thompson, B. B. Thayer, R. L. Agassiz, Chas. M. MacNeill, Urban H. Broughton, and Thomas W. Lamont. The occasion was evidently a Guggenheim affair. The host is the head of the house of Eugene Meyer, Jr., & Co., one of the large houses on the New York Stock Exchange, and is looked upon in banking circles as an ally of J. P. Morgan & Co. The Guggenheim interests are largely backed by Morgan & Co., and it was Mr. Perkins, of the Morgan house, who went to Alaska last year on a trip of inspection, covering the Morgan and Guggenheim mining and railway enterprises. Mr. Perkins has recently announced his early retirement from the banking firm, and it is said in many quarters that this is a preliminary step toward his becoming the financial head of a copper consolidation, in which he would presumably stand primarily for the Guggenheim companies. Mr. Lamont is to enter the Morgan house when Mr. Perkins goes out. Mr. Agassiz' presence is taken to mean that the Lake coppers are to recognize the exigencies of the situation. The present line-up in copper is very interesting. It is quite patent that the much-talked-of curtailment policy has failed to curtail effectively. There has been some reduction of the world's accumulated stock, all due, however, to an unprecedented foreign demand. It is to institute some regulation of output, that will save the metal market, that these dinners have been given. There is in sight the product of the developing low-grade milling coppers, and the necessity of some such action is apparent. It is believed on all sides that a copper merger will eventually result as a matter of necessity. It goes without saying that, when it does come, the banking interests will see that it is so constructed as to furnish some hundreds of millions of stock, to be sold to the public. The export demand for copper cannot be expected to maintain its present strength indefinitely. Actual exports for November were 60,882,000 lb., as against 48,056,000 for the same period a year ago, an increase of nearly 13,000,000 lb.; and with any material decrease in the foreign demand, the copper market would become weak. There is hardly a day without some item indicating a narrowing or unifying of the copper interests. J. Parke Channing, engineer for the Lewisohn interests, has been in the Lake Superior copper district for three weeks and is said to be engaged in making an appraisement of the subsidiary properties of the Calumet & Hecla company, preliminary to making that company a holding company for various Lake Superior properties. This is in line with plans for a general copper merger. There is certainly great significance in the fact that the Calumet people should employ an engineer affiliated with the Amalgamated interests in an examination of their properties. Mr. Channing has been in Boston for nearly a week in conference with the Calumet & Hecla officials. Ray Consolidated and Chino are to join Utah Copper and Nevada Consolidated on the New York Stock Exchange. Boston & Montana is to be dissolved, all of its property having been sold and transferred to the Anaconda. The only asset it now holds is 1,200,000 shares of Anaconda which is to be distributed to Boston & Montana shareholders. Each share of Boston & Montana will receive eight shares of Anaconda. On the present market of $40 for Anaconda, Boston & Montana would have a market value of $320 per share. The last sales of Boston & Montana were considerably above this figure. The recent consolidation of the Calumet & Arizona and the Superior & Pittsburgh, while not particularly significant, is in the line of solidification. The consolidated company will be one of the first six or eight large producers of the country; the combined production of the two mines for November was 4,090,000 lb. While the Cole-Ryan group is strengthened by this move in Bisbee, there are weak links at Ely and in Cananea. Neither Giroux nor Greene-Cananea seem to have a friend in the market place. Greene-Cananea's 50,000,000 capitalization appears to wholly offset any rebuilding of the plant or reduction of copper costs, while Giroux is suffering from a lack of definite news. Most of the copper mines now developing have been giving out statements of ore developed and progress made, while from the Giroux there has been nothing forthcoming. The situation in Utah Consolidated has been an adverse market factor. It is said there was some heavy buying on the break by some interests who were not inclined to believe the worst. The $3,000,000 of 6% convertible bonds of the Ray Consolidated are said to have been all taken by the stockholders at par. Generally speaking, market conditions are unsatisfactory. There is an utter lack of leadership, and no cohesion in any part of the list. This is illustrated by the great variations in prices with reference to income. Chino, Miami, Ray Consolidated, and Nevada Consolidated are selling at practically the same figure. The initial production of the first three is still several months in the future. On present quotations Nevada Consolidated, at 18½, nets 8.1%; Utah Copper, at 46, 6.5%; Anaconda, at 40, 5%; Amalgamated, at 63, 3.2%. On the other hand, dividend-payers like Kerr Lake and Goldfield Consolidated, netting from 21 to 26%, do not enlist enough public support to bring the shares to anything like a parity with other dividend payers. The regular quarterly dividend of 30c. per share, together with an extra dividend of 20c. per share, has been declared by Goldfield Con., payable January 31 to stockholders of record December 31. The impression here is that a systematic campaign is being made to distribute this stock. The market shows it, and both the public and the stockholders are without sufficient data to form any conclusion as to the future life of the mine. The good news seems to appear after the quarterly declaration and while the shares sell 'with dividend.' There is no tendency to belittle the accomplishments of this mine, nor any ground to doubt its future. It is simply that shareholders are without adequate data, while the market shows that someone is 'cashing in.'——It is said that the French interests in Mexico Mines of El Oro have secured control of the property and that a change in the management is one of the possibilities of the near future. Cobalt dividend-payers are making a rare showing for the close of 1910. The Canadian Silver Mines Exploration Co., which is a subsidiary of the General Development Co., has taken up its option on the Wettlaufer in South Lorain. The Lewisohn interests have had charge of the Wettlaufer for several months and actual operations have been under the superintendence of Mr. Heakes, general manager of the Kerr Lake.

General Mining News

ARIZONA

MOHAVE COUNTY

(Special Correspondence).—The Tom Reed Gold M. Co. has been operating in the Goldroad district for three years, and has its mine opened by an incline shaft, which was sunk in the foot-wall, and has a depth of 500 ft. Driving on the vein is in progress on the 300 and 400-ft. levels, and a winze is being sunk from the 400 to the 500-ft. level. The vein strikes northwest through andesite, dips 73° north, and has a width of 5 to 20 ft. The 20-stamp mill is crushing only 50 tons per day at present, the extraction by amalgamation and the all-slime process of cyaniding reaching 95 to 97%.——At the Gold Road mine the new development consisted of driving 960 ft. east on the 700-ft. level, and 1500 ft. east on the 500-ft. level. Ingersoll and Sullivan drills are being used in driving, the Leyner for stoping. The new mill, having 40 stamps, two Trent Chilean mills, and two tube-mills, has a capacity of 300 tons per 24 hours.

Goldroad, December 12.

(Special Correspondence.)—The Cyclopic mine, 35 miles north of Chloride, is being developed under direction of A. M. McDuffee. It is bonded and leased to T. T. Powell, of Pittsburg. Surface development has exposed one orebody which is on the contact of granite and schist. Deeper development is being carried on by diamond-drills.——Sam Rhea has a contract to sink to 1000 ft. on the Tennessee, at Chloride, so the orebodies may be opened at that depth. The large tonnage of ore on the Tennessee dump, which samples $4.50 gold per ton, 5% lead, 16% zinc, and 12% iron, is being shipped to the concentrating mill of the Needles Mining & Smelting Co.——The Golconda mine of the Union Basin M. Co., situated in Cerbat district, is a heavy producer of zinc, the ore shipments showing 47 to 52% of that metal, and sufficient value in gold and silver to pay operating expenses. John Boyle, Jr., is the manager.——The Banner and other properties on Stockton hill are being developed by the Needles M. & S. Company.

Chloride, December 15.

YUMA COUNTY

The Consolidation Copper Co. has 140 mining claims, covering 12 miles of what is considered a mineralized zone in Cieniega district, south of Bill Williams fork, about equidistant from Bouse and Parker. Active as directors in the company are Thomas J. Carrigan, R. I. Rogers, and Frank Robbins, the last-named being consulting engineer. S. F. Parrish, formerly at Leadville and Rossland, is in charge of operations. According to Mr. Parrish's report of September 21, the work performed for assessment and development purposes aggregated over 3000 ft. at that date. One shaft has a depth of 200 ft., and from it two crosscuts, 25 and 59 ft., respectively, were driven through the vein; a 282-ft. adit was driven, partly as a cross-cut and partly on the orebody. Along the zone is a cropping of specular iron and red hematite, accompanied by azurite, malachite, chrysocolla, and cuprite; also some chalcocite and chalcopyrite. The ore occurrence varies along the belt, and is found in bedded veins in gneiss, on the contact of gneiss and limestone, and gneiss and intrusive rock. Mr. Robbins states that the assays of the orebody sampled averaged 8% copper. This group is in the same locality as the Planet and Clara mines.

CALIFORNIA

AMADOR COUNTY

The Lincoln Con. M. Co. sank 150 ft. in the last quarter, and now has a 300-ft. shaft. The ore broken runs $4 to $5 per ton. For the quarter the company disbursed $8211.72 for labor, salaries, equipment, material, and supplies, and had a balance December 15 of $3356.26. On December 10 assessment No. 3, of 10c. per share, was levied. The company's office is at Jackson.

CALAVERAS COUNTY

The Economic mine at Esmeralda is being equipped with an extraction plant by which 200 tons per day can be treated. It is claimed there are 3000 tons of ore broken in the stopes. Other equipment to be put in consists of an air-compressor, generator for electric light, and a steam boiler. V. M. Weil is manager, and Oliver Reece is superintendent.

NEVADA COUNTY

The Coan mine, in charge of Dan McGonigal, has a new shaft-house and hoisting engine ready for use. The new mill building is complete, and the ten stamps, plates, and concentrating tables are ready to be put in place. The new shaft, only recently commenced, is to be sunk to a depth of 200 ft.——The Cassidy Con. M. Co., operating in Grass Valley district, has purchased a 100-hp. electric motor to drive the compressor. The shaft is to be sunk to a depth of 1200 feet.

SISKIYOU COUNTY

It is reported at Yreka that the Southern Pacific Co. contemplates building a railroad from the main line to Crescent City, Del Norte county, a distance of 70 miles, to reach the vicinity of the copper mines in western Siskiyou, notably the Blue Ledge, which belongs to Robert S. Towne and associates, who have had the property under development for several years. It is reported also that the Hill people have outlined a route from Medford to the Blue Ledge district which is four miles south of the Oregon-California boundary line.

SAN BERNARDINO COUNTY

(Special Correspondence.)—The smelting plant of the Needles Mining & Smelting Co. has two lead furnaces which

Concentrator Needles S. & M. Co.

have been in operation five months, treating 200 tons of ore per day, deriving the ore supply from the company's mines in the Cerbat range in Mohave county, Arizona, and from custom mines. A concentrating plant of 250 tons capacity was finished and put in operation last month to concentrate low-grade lead-zinc-iron ores. It is equipped with 22 Wilfley tables, one Isbell and three Johnston vanners, one Deister sand table, three Richards pulsator jigs, four Richards classifiers, one tube-mill, and two sets rolls. Under direction of M. B. Pickel, mill superintendent, tests are being made as to the adaptability of the various tables and vanners to concentrate the classes of ore received.

Needles, December 16.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A contract has been awarded to John Hansen to drive 700 ft. westerly on the Santiago vein from the Wilcox adit. When the work is completed a 500-ft. raise is to be made to connect with the upper workings of the Santiago mine. Ore shipments from the Santiago amount to six carloads per week, having an average value of $1000 per car. The Argentine Central railroad will be kept open all winter to haul this product. B. Converry & Co., leasing at the Capital mine, are breaking ore from a 14-in. streak that mills 10 oz. gold and 35 oz. silver per ton, with 60% lead and 5.5% copper.——Work was resumed last week at the Stemwinder mine, on Columbia moun-

tain; an adit is to be driven 150 ft. to intersect the vein at an increased depth of 80 ft. G. J. Hite is manager.——A shipment of six tons of ore was made last week from the Angio-Saxon mine on Saxon mountain that brought a settlement of 3.50 oz. gold and 32 oz. silver per ton. A. Robert is operating it under bond and lease.——A body of ore two feet wide has been found in the bottom of the 60-ft. shaft on the Jersey Blue, situated in the Daily district. Tests show values of $60 per ton in gold and silver.——The Bard Creek M. Co., operating on Lincoln, has advanced the lower adit 225 ft. It will be necessary to drive 200 ft. before the Nelson vein is intersected.——The Hidden Treasure mine is being developed and occasional shipments of ore are being made.——The Lincoln adit is expected to tap the 500-ft. station of the Virginia City shaft within the next 40 ft. F. A. Maxwell is in charge of the work.——Heavy shipments of lead and zinc concentrate are being made from the Pelican mill. The lead product which carries silver is worth $60 per ton.——A discovery is reported at the Smuggler mine, on Brown mountain, where a 10-in. streak of galena was opened in the breast of adit No. 2, that mills $64 per ton in silver and lead. J. R. Sapp is manager.

Georgetown, December 12.

GILPIN COUNTY

The Frontenac Con. Mines, Ltd., owns the Frontenac and Adduddel mines, having the Adduddel vein, on which there are 20,000 ft. of underground work on the two properties. It is claimed there is a big tonnage of ore exposed by those workings, the grade of which is $6 to $12 per ton, the metals being gold, silver, lead, and zinc. The group was cut by the Newhouse tunnel at a depth of 2000 ft. on the dip of the vein. The Adduddel and Frontenac workings extend only to the seventh level, leaving vast unexplored ground between that and the level of the Newhouse tunnel. Henry P. Lowe and Sydney B. Tyler are manager and engineer, respectively, and under their direction a 250-ton mill is being built on the site of the Penn mill at Black Hawk. It is being equipped with a crusher, rolls, classifiers, tube-mills, concentrating tables, and slimers. Systematic tests, carried on more than a year, convince these operators that with the mill being constructed it will be possible to recover 80 to 90% of the gold, 60 to 70% of the silver, 75% of the lead and copper, and practically all of the zinc. It will be noted that the plan of this mill represents a radical departure from the old Gilpin county mill practice.

LAKE COUNTY

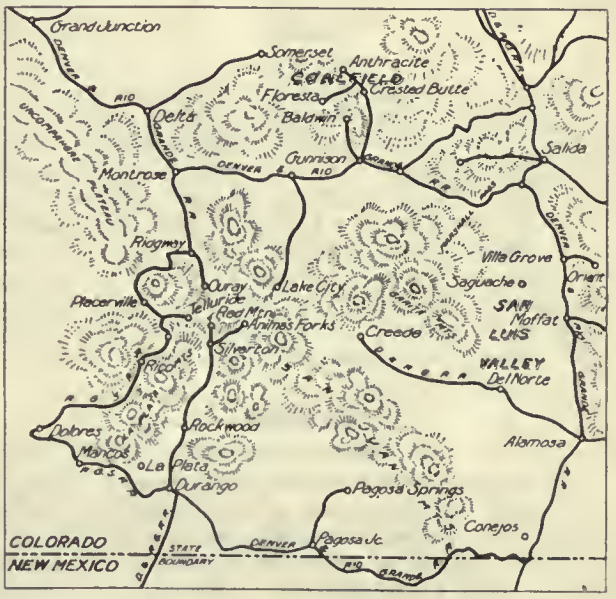
The lessees of the Lime mine, on California gulch, have a contract to ship zinc-carbonate ore to the Exceisior zinc works in Missouri. The terms of the contract allow the shipment of ore running as low as 20% zinc; this is a concession not heretofore given, 25% having been previously the minimum. It is predicted that other zinc buyers may meet this reduction in grade of ore that will be received.——The ore shippers on Breece hill are the Highland Mary, Penn, and Big Six; operators of the Bertha, Curran, Grand Prize, President, and Little Galesburg are active in exploring for ore.——The Clear Grit, on Iowa gulch, managed by C. J. Moore, has a pumping plant, and by keeping the water out, the shaft-sinking can progress. Within a month it is calculated that the first contact will be cut by the shaft. When that point is reached a station is to be cut, and a level driven to the Helena ore-shoot.——The lower levels of the Helena mine, Iowa gulch, are filled with water, and the pumping station is also submerged to a depth of 110 ft. Divers who succeeded in starting submerged pumps in the Smuggler mine at Aspen were here to start the Helena pumps, but were unable to reach them, on account of an obstruction in the shaft.——George Cramer, a lessee at the Waterloo shaft, Carbonate hill, is making daily a shipment of 30 tons of zinc-carbonate ore which exceeds 30%. The ore is being mined on the 450-ft. level.——About the first of the year some of the leases on Leadville mines will terminate and the properties will then be operated on company account; many other leases will be renewed at this time. The opportunity for the lessee of ordinary means has been to mine bodies of ore overlooked in early-day operations; this method has not resulted in much development. But with the search for zinc-carbonates now going on a development era has commenced. The *Carbonate Chronicle*, of Leadville, estimates the average value of zinc-carbonate being shipped at $20 per ton. Close to 4000 tons of this class of ore per month is being mined in the district.

SAN JUAN COUNTY

A shoot of lead-iron-zinc sulphide ore has been opened on the third level of the Ledge mine, said to be 350 ft. long, 5 to 20 ft. wide. About 100 tons of this ore is being concentrated per day, by which two products are made—one running 50% lead, the other 40% zinc. Later the mill will have reached its normal capacity, which is 200 tons per day. The mine is between Silverton and Red mountain.——The North Star mill, at Silverton, is operating part time.——The Iowa mill is being operated on ore produced by the Iowa-Tiger Leasing Co., concentrating 400 tons per day, and shipping 20 cars per month of lead concentrate.

SAN MIGUEL COUNTY

The November production of this county showed an increase over previous months. The total for 1910 is esti-



Map of Southwestern Colorado.

mated at $3,344,000. The mining of ore containing vanadium has contributed considerably to the county's industry.

SUMMIT COUNTY

William Jacobs, of Georgetown, who has been developing the Star group in Peru camp the past year, recently opened a narrow vein of ore, samples from which assayed 800 oz. silver per ton. The ore contains silver glance, copper, and bismuth.——The Wilson, Breen, and Michigan mines are the most active properties at Kokomo. The Wilson has a force of 90 men.

TELLER COUNTY

(Special Correspondence.)—Stratton's Independence, Ltd., for the first half of the fiscal year (December estimated), shipped 9386.44 tons of ore of the gross value of $228,900; and milled 50,353 tons of low-grade ore having a gross value of $150,000. The mill, which was recently enlarged to give it a capacity of 9000 tons per month, is successfully treating sulpho-telluride ore grading as low as $3 per ton, and is earning 10% on the entire capital of the company. The process consists of crushing and concentrating in cyanide solution, the sand and slime tailing being cyanided separately. The plant has been in operation since March 1908. This company paid on November 30, dividend No. 4, of $60,000, or 6c. per share, free of income tax. Philip Argall & Sons are consulting engineers and acting managers for the company.

Victor, December 17.

(Special Correspondence.)—The Cresson Con. Gold M.

Co., of Chicago, owns and operates the Cresson mine, situated between Battle mountain and Raven hill, Cripple Creek district. The mine is opened by a 1200-ft. two-compartment shaft. Ore is being mined on the 400, 500, 700, and 1000-ft. levels, and the ore-shoot is being opened on the 1200-ft. level, which is the water-level at present. The Cresson is within the basin which is being drained by the Roosevelt tunnel. In 1909 this mine ranked third, in tonnage of ore produced, among the properties of the district. The shaft-house and plant were destroyed by fire April 11, 1910, and were replaced and ready for use by July 11. Richard Roelofs, the manager, took charge four years ago.

Cripple Creek, December 9.

Vanatta and associates, lessees on the fifth level of the Ajax, Battle mountain, recently opened a body of ore 11 ft. wide, a 5-in. streak within it assaying 27 oz. gold per ton. A shipment of the rich ore was made. Fogleman & Vaughan, having a lease on a block of ground in the same mine, lately shipped two cars of ore which sampled about $100 per ton. The 25 sets of leases on the Ajax, nearly all of which are profitable, yield a tonnage of ore that makes this property one of the large producers of Cripple Creek district.

IDAHO

BOISE COUNTY

(Special Correspondence.)—The Gold Hill & Iowa Mines Co., operating its mine and mill at Quartzburg, has been milling ore from a new orebody found on the 500-ft. level during the past month. Lessees working on the Confederate claim of this group milled ore which yielded $30 per ton by amalgamation in a Lane mill. The sub-station on the company's power-line recently burned down, and pending the installation of a new one the water in the shaft rose nearly to the 400-ft. level, as electric power was depended on for pumping. E. E. Carter, the manager, states that extensive development is to be carried out next year.

Quartzburg, December 17.

KANSAS

CHEROKEE COUNTY

The old Lawton camp northwest of Galena is being revived under the management of Walter Ragland and associates. A centrifugal pump has been installed to unwater the ground, power for which is supplied by the electric company, so that work can be started at once. It was well prospected by drilling many years ago and was considered worth developing.——Joe Fahlenbach, manager for the Clermont company, operating on Shoal creek, south of Galena, is planning deeper development. The land belonging to the company has been tested to a depth of 300 ft. and the levels from 140 to 300 ft. were found to be mineralized.——Franklin Playter, who drained the Southside tract and leased 80 acres of it, has let a contract for about 2000 ft. of drilling, to determine the condition of the 250-ft. level where ore is said to exist.——The new Petersburg mill, in the Quawpaw camp, is modeled after the Eastman Investment mill, which proved a success in treating the difficult ore in that camp. This ore requires different treatment from the Joplin ore, hence the need of different equipment. The mill is equipped for complete sizing, has six sets of cleaner jigs, but no rougher jigs. There is also a department in which the fine is well taken care of. The mill has a rated capacity of 400 tons, and it is expected to be in operation by January 1.——The Tlawaugh company opened several veins of ore while sinking. They vary from 6 to 8 inches in thickness. There is a mill on the lease, and this mine is classed among the better properties of Galena camp.——The Hella company, at Cave Springs, sank a shaft into a new deposit, finding ore running 5 to 40%. An 8-ft. face of ore is in evidence in a drift that was run from the 130-ft. station.——The Homestake company, at Peacock, has purchased the Cincinnati mill and will move it to the lease. A new body of ore was discovered in the Homestake and some of the ore was tried out on hand-jigs.

Galena, December 10.

MISSOURI

NEWTON COUNTY

(Special Correspondence.)—The Spring City camp is more active than at any time for a year. A new mill has just been completed and put in operation by Creech & Co. on the site of the old Delta mine. They have had this mine under development for some time. The old Delta company abandoned the mine and removed the mill. Creech & Co., after cutting new ground, found ore consisting of calamine and lead.——Arthur Scott is sinking a shaft on the Craycroft land on which excellent ore was found at 180 ft. by drilling. The formation here is the same as that of the Delta. The ore occurs beneath a cap-rock of limestone.——The Alpha, managed by Adam Scott, is operating after an idle period. This is the first producer in the camp and has made a good record. The mill was recently re-equipped as a concentrating plant and will now treat the ore direct from the mine. The ore runs about 10%.——The U. G. Wilson company has the Ohio Valley mill, which is being overhauled and put in order to operate on ore from the Wilson lease. A derrick and hopper are being built and a tramway will be built from the new shaft to the mill. The Ohio shaft is also being reopened.——The La Plata is being reopened and equipped with a derrick, ore-hopper, crusher, hand-jigs, and hoister, by Kaufman & Patterson.

Granby, December 17.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—The New Year Gold Mines Co. has sold its mine and cyanide plant, situated near Maiden, Judith basin, to the Reingold Mining Co. of Chicago. Joseph Meredith, who has been superintendent of the property for ten years, has tendered his resignation to take effect December 31.

Lewistown, December 18.

NEVADA

CLARK COUNTY

Lessees of the Chief of Hills mine have made a run of 75 tons of their ore at the Cyrus Noble mill, at Searchlight, recovering over $3000 as the result. The Yellow Pine M. Co. is erecting a concentrator at Goodsprings. Shipments from the latter camp amount to 20 tons per day, the ore being mostly zinc.

NYE COUNTY

The Rawhide Coalition Co., directors of which are E. W. King, H. R. King, J. H. Barrett, M. Sheeline, and S. A. James, has decided to purchase the Rawhide Queen mill for treating the ore of the Coalition company at Rawhide.

STOREY COUNTY

Last week's production of the three principal north end mines on the Comstock were: Ophir, $10,785.75; Con. Virginia, $517.40; Mexican, $1834. The 185 mine cars from the Ophir, taken from the 2100-ft. level, averaged $56.87 per ton, and 22 cars from the 2300-ft. level averaged $11.98. The ore from the Con Virginia, 85 cars, was mined on the 1800-ft. stope and ran $6.08 per ton. The Mexican's tonnage consisted of 27 cars from the 2200-ft. level, running $24.04; 47 cars from the 2300, averaging $14; 60 cars from the 2350-ft. level $5.75; 15 cars from the 2500, $12.17 per ton. The principal development in the Ophir consists of sinking a 3-compartment winze from the 2200-ft. level. It has reached a depth of 25 ft. below the 2400-ft. station, and is to be sunk to the 2500-ft. level. Work of driving and stoping is in progress from the 2300-ft. station of this winze.——The Charles Butters, Co., Ltd., has leased its concentrating mill and cyanide plant in Six-Mile canyon, below Virginia City, to Joseph Dietrich and Hahnewald Bros. of Leadville, Colo., who have a lease on the upper workings of the Chollar and Potosi mines. The lessees began operating the concentrator the next day after the lease was signed, and the cyanide plant is to be started as soon as there is a sufficient accumulation of slime from the concentrators. They anticipate milling 150 tons of ore per day. The former millmen are retained.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co. treated 584 tons of ore for the week ended December 3, extracting therefrom 6000 oz. of gold and silver bullion, and producing 60 sacks of concentrate.——The Socorro Mines Co. milled 900 tons of ore for the week, producing concentrate on the tables, and a gold and silver precipitate in the cyanide plant. A large tonnage of the ore mined was incidental to development work.——The Gold Dust Mines Co. is active in establishing a camp. A storehouse, boarding-house, and blacksmith-shop are nearly finished. In the mine driving is in progress from the cross-cut adit.——The Mogollon Gold & Copper Co. is installing a steam hoist, and three tanks are being set up for the storage of fuel oil for steam boilers. A machine-shop and assay office are being built. At the same time mine development is in progress.——Operators of the Deadwood mines have driven a cross-cut on the 500-ft. level to the Last Chance vein. Progress is being made building the mill.——The Treasure Mining & Reduction Co. has teams at work hauling ore from the mine to the mill, most of the ore being taken from the ore-body recently discovered on the foot-wall of the lode.

Mogollon, December 4.

(Special Correspondence.)—Forty men are employed at the Deadwood mines. The mill is nearly finished, the pipe-line for water supply is all laid, and the telephone line from Mogollon to the mine is being established.——The week's tonnage of ore milled by the Ernestine M. Co. was 679, the product having been 56 sacks of concentrate, and 6926 oz. of silver and gold bullion. Some of the richest ore is being taken from the eleventh level west, which contains free gold and native silver.——At the Socorro mill 800 tons of ore was treated for the week, and creditable shipments of bullion and concentrate were made.——Two shifts of miners are at work in the Gold Dust mines, and driving is in progress both east and west from the cross-cut, the headings being on a 4-ft. vein.——The first and third levels are being driven south in the property of the Enterprise M. Co.——Work has been started by contractors on the north drift of the Admiral Dewey claim, situated on the Mother Lode.——At no period in its history has the district received such intelligent development as at present. The discovery of new ore-zones and the proving of known bodies at greater depths is of weekly occurrence, and it would now seem that production will be doubled the coming year.

Mogollon, December 10.

OREGON

BAKER COUNTY

The United States Smelting, Refining & Mining Co. has bonded the Rainbow mine at $1,050,000, having four months in which to examine the property and decide as to taking up the bond. The conditions require the payment of $250,000 cash if acceptance is made at that time. The Rainbow is a gold mine, belonging to the Commercial M. Co. of Portland, and is situated in Mormon basin, 30 miles southwest of Huntington. The mine and mill have been steadily operating for six years.

WASHINGTON

FERRY COUNTY

The Knob Hill M. Co., having a lease and bond on the Knob hill claims at the forks of Eureka gulch, Republic, is believed to have the northern extension of the Lone Pine-Surprise lode. Recent driving on the vein demonstrated that the ore has an average width of 2 ft., and that it is 7 ft. wide at the present face of the drift. Samples taken across the face on three consecutive days assayed $174, $120, and $216, respectively. Shipments from the mine amount to one car per week, the smelter returns running $1800 to $4700 net per car. The company's manager is J. W. Lloyd, who is having another adit level driven which is to cut the orebodies at greater depth. The Knob Hill formerly belonged to J. Browne, who bonded it to this company.

WYOMING

ALBANY COUNTY

(Special Correspondence.)—The Rambler Copper & Platinum Co., operating at Holmes, 50 miles west of Laramie, in Medicine Bow range, has made some changes in its mill whereby it is expected soon to be treating 150 tons of ore, with a resultant production of about 1000 lb. of platinum concentrate per day. A. C. Dart is general manager for this company.

Holmes, December 15.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—Work on the Mayflower lease in the South Belt shows ore in the main vein assaying $50 per ton. The Nickel Plate lessees continue regular shipments to Trail and expect to work all winter.——The Le Roi No. 2, Ltd., for October produced 2250 tons of ore and 134 tons of concentrate, which returned $25,766. The estimated expenditure was $8000 on development, $15,000 on ore production, and $1250 in milling, a total of $19,750. Work in the principal workings was advanced 314 ft.——The ore shipments from Rossland district for the week ended November 26 were: Centre Star, 4182 tons; Le Roi No. 2, Ltd. (part concentrated), 542; Le Roi, 315; Nickel Plate, 29 tons.

Rossland, December 3.

(Special Correspondence).—The Granby Con. M. S. & P. Co. has announced a dividend of $1 per share, amounting to $150,000 on its outstanding stock. This makes a total of $3,928,630 paid in dividends to date. During October this company shipped 1,154,234 lb. copper. Eight furnaces and four converters are in operation. Last week the shipments of blister copper amounted to 348,000 lb. The main vein has been cut in the tunnel at the No. 7 mine of the Consolidated company, and a new and lower adit will be driven. A crushing plant is to be installed at the mine. Diamond-drill work is being done on the Alma and Fairplay claims of the Snowshoe group.——The ore shipments from Phoenix district for the week ended December 3 were as follows: Granby Mines, 18,354 tons; Jackpot, 400; Mother Lode, 7784; No. 7, 37; Rawhide, 4000; Snowshoe, 3833 tons.

Phoenix, December 10.

(Special Correspondence.)—It is reported that the Standard mine, near Silverton, is about to change hands, on a basis of about $400,000. The lode on this property is exposed in six adits, and a seventh is being driven. The ore carries 70% lead and about 100 oz. silver per ton. The ore mined is being shipped to Trail.——The Crows Nest Pass Coal Co. has closed down some of its Coal creek mines and will reduce the output to about 3000 tons per day. The total tonnage of all of the company's mines has been averaging over 6000 tons per day.——The shipments of ore and concentrate from this district for the week ended December 3 were as follows: Buffalo, 2 tons; Fisher Maiden, 11; Flint, 20; Hope, 30; Richmond-Eureka, 32; St. Eugene (concentrated), 138; Silver Cup, 28; Sullivan, 580; Utica, 19 tons.

Nelson, December 10.

The British Columbia Copper Co., under the management of J. E. McAllister, operated three copper furnaces during the month of November, smelting an average of 2000 tons per day. The ore supply is derived from the company's Mother Lode mine, near Greenwood, and from the mines of the New Dominion Copper Co., situated mainly in the Phoenix district. The B. C. Copper Co. owns 64% of the shares of the New Dominion company, and for several months has exercised control over the latter's mines. The ores of the Mother Lode mine carry enough gold, when credited to copper production, to enable the B. C. company to produce copper and deliver it in New York at about 8c. per pound.

MEXICO

HIDALGO

The La Reina company has acquired the adjoining San Pablo property of 24 *pertenencias*, taking in part of an important lode of the Pachuca district.

Book Reviews

Any of the books noticed in this column are for sale by or can be procured from, the MINING AND SCIENTIFIC PRESS.

A GUIDE TO TECHNICAL WRITING. By T. A. Rickard. Second edition. Pp. 172. Index. *Mining and Scientific Press*, San Francisco, *The Mining Magazine*, London, 1910. Price $1.

The wide interest aroused by the first edition of this book has encouraged Mr. Rickard to prepare a second. In doing so he has taken advantage of the opportunity to revise the text thoroughly and to add much new matter, including his paper on 'Standardization of English in Technical Literature' that provoked so lively a discussion when read before the Institution of Mining and Metallurgy last May. Mr. Rickard writes vigorously and with the energy of a reformer who has campaigned with Mr. Heney. He puts things strikingly and provokes the reader to search that he may find errors in the rules laid down. All this is excellent, since, as he well says, "Whether my views prove acceptable or not is a small matter; my aim in addressing you is * * * to direct your attention to the intelligent use of words in technical writing." This he has certainly done. Since he read at Denver in 1901 his 'Plea for Greater Simplicity in the Language of Science' there has been much searching of dictionaries, by Mr. Rickard's readers as well as by him. Probably few will accept all his statements and rules, but all who have read his various articles on technical writing have thereafter written more carefully. "The attempt to state useful rules may read like an effort to establish irrefragable laws," he says, to which I would add that it certainly does, but to accept the rules as absolute is to mistake the author's purpose. He puts the whole thing nicely in the preface: "Reformers do not wait until they receive official appointment. Such as I have I give. I write as a scribe, without authority, except in so far as the members of my old profession will concede it to me from the nature of my present occupation; I speak as a student, not a master; as an amateur who has become a professional, but not a professor."

The book is most attractively written and is thoroughly interesting. It is at the same time informing and is the best practical guide to correct writing available to engineers. That in the main Mr. Rickard's suggestions are good, is evidenced by the extent to which they have been adopted since the appearance of the first edition of the book. The official action of the Chemical, Metallurgical & Mining Society of South Africa in adopting his more important recommendations indicates that engineers are willing and anxious to write well when shown how. The hint might well be taken by those who plan courses of study in engineering schools. It is as great a handicap to a graduate of an engineering school to have been given poor or no instruction in his native tongue as to have been imperfectly taught in chemistry or mathematics. H. F. B.

THE AMERICAN RED CROSS ABRIDGED TEXT-BOOK ON FIRST AID. By Charles Lynch. Pocket size. Pp. 183. Ill., index. P. Blakiston's Son & Co., Philadelphia, 1910. Price 30 cents.

This little volume has been prepared with a view to educating the public in rendering 'first aid' to the injured, and covers a wide range. Accidents occur all around us daily, in the city streets and buildings, on the farm, in the mines and metallurgical works. The book teaches how to bandage injuries, to administer stimulants, to treat persons shocked by electric currents, to carry an injured person, and many other things calculated to temporarily aid the victims of accidents until medical assistance can be secured. It is a very valuable and humane little work and should be available at every mine.

THE MYSTERY OF BONANZA TRAIL. By Frank J. Arkins. Pp. 128. Ill. The General Publishing Syndicate, Denver. Price $1.

This is a story of mining, such as is seldom read in popular magazines. The author treats his subject intelligently for the most part, and works it up to a successful and dramatic climax. The story is woven around a group of rich mines beset by almost interminable litigation over apex control and extralateral rights. The legal battle waged is certainly complicated enough to suit the most exacting, though no worse than has been fought in a dozen Western camps. The scene may well have been in the San Juan mountains of Colorado. The little story is full of life, information, and entertainment.

GOLDFIELD CONSOLIDATED FOR NOVEMBER

The following preliminary report of the operation of the Goldfield Consolidated Mines for November 1910 has just been issued by the general manager, J. R. Finlay:

TONNAGE PRODUCED

	Dry tons.	Average oz. per ton.
Combination	4,778	0.89
Mohawk	7,695	0.87
Red Top	4,237	1.03
Jumbo: Milling ore	8,031	2.38
Shipping ore	215	35.11
Total	24,956	1.68

The gross value to be credited to the various mines is as follows: Combination, $87,900; Mohawk, $138,350; Red Top, $90,200; Jumbo (milling ore), $395,000; Jumbo (shipping ore), $156,000; total, $867,450.

The performance of the mill was as follows: dry tons milled, 24,741; average value per ton, $28.76; total value, $711,450; loss in tailing, $55,236; value realized, $656,214; percentage extracted, 92.24.

EXPENSES

	Amount.	Average per ton.
General:		
Bullion tax, income tax, and marketing bullion	$23,500	
Administration, etc.	18,000	
	$41,500	$1.66
Mining	88,000	3.53
Marketing high-grade ore	13,500	0.54
Transportation	3,000	0.12
Milling:		
Milling and cyaniding $57,500		
Marketing concentrate res. 16,500		
	$74,000	2.99
Construction	4,600	0.19
Net cost	$224,600	$9.00
Loss in tailing	55,236	2.21
Total costs and losses	$279,836	$11.21

Profit per ton, $23.55; total value of ore per ton, $34.76; total profit for month, $587,614; percentage of profit, 67.74.

The manager says: "The long progress of construction is in process of winding up. We may now count on economies in power and supplies. The electric storage-battery plant is in successful operation, and it is expected to effect a saving of $2500 per month. The new assay office is so far along that the process of moving in will begin immediately. The new refinery at the mill has been partly tried out and we are confident of saving $5000 per month by its use. Only the delayed arrival of some material has prevented its final completion before this. The new heating plant at the mill has apparently already paid for itself by the improvement it has accomplished in precipitation. The new compressor for the mill has been greatly delayed and will not be installed before January 1."

The advance made in the various mines for the month was as follows: Combination, 419 ft.; Mohawk, 1264; Red Top and Laguna, 857; Clermont, 1125; total, 3665.

The only ore of consequence opened on new levels during the month was in course of development on the 1000-ft. level of the Clermont. This produced 509 tons of ore that averaged by mine assays 5.01 oz. per ton.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

MARK R. LAMB is at Lima, Peru.

EDMUND JUESSEN is at Blair, Nevada.

W. W. MEIN has been in San Francisco.

W. J. LORING is expected in San Francisco.

A. F. MILEY was in San Francisco last week.

J. NELSON NEVIUS was in San Francisco this week.

COREY C. BRAYTON was in San Francisco last week.

EARL DISSINGER has returned from Mexico and is at Amos, Nevada.

GELASIO CAETANI has returned to San Francisco from Nicaragua.

LIONEL LINDSAY is at Alamos, Mexico, for the Pacific S. R. & M. Company.

NORMAN C. STINES is at St. Petersburg for the Russian Mining Corporation.

VICTOR G. HILLS is examining a tungsten mine in Halifax county, Nova Scotia.

M. EISSLER has been at St. Petersburg recently in connection with negotiations regarding his concession in the Trans-Baikal region.

SAMUEL J. WEIS has gone to Axim, Gold Coast Colony, West Africa, to supervise dredging for the Ancoba Exploration & Dredging Co., Limited.

WALTER CURRIE, consulting engineer for Willoughby's Con. Co., Ltd., Buiawayo, Rhodesia, was in San Francisco, and has gone to Deadwood, South Dakota.

JOSEPH MEREDITH, for ten years superintendent of the New Year mine and mill near Lewistown, Montana, has resigned on account of the sale of the property.

OBITUARY

STEWART WATT, vice-president and superintendent of the Watt Mining Car Wheel Co., died at his residence at Barnesville, Ohio, December 10, at the age of 64. He was ill but a few days with bronchial pneumonia. Mr. Watt was, with his brother who died several years ago, the joint inventor of the first self-oiling mine-car wheel, and for the last thirty-five years has been actively engaged in the manufacture of mine-car wheels. He first operated a foundry in 1863.

DECLINE IN FOREIGN VISIBLE COPPER

The decrease of 1,072,960 lb. in the foreign visible supply of copper in the two weeks ended December 1, makes a total decrease of 60,995,200 lb. since March 1. Foreign stocks of 193,155,140 lb. are now at lowest point since August 1909, when they amounted to 171,492,160. The high point was 254,150,400 lb. in March of this year.

The United States surplus, foreign visible supply, and total of the two since January 1, 1909, in pounds, as tabulated by the *Boston News Bureau*, is given below.

	U. S. surplus.	Foreign visible supply.	World's surplus.
January, 1909	122,357,266	124,716,480	247,073,746
July, 1909	154,858,061	150,928,960	305,787,021
January, 1910	141,766,111	244,205,800	385,970,911
February	98,463,339	248,236,800	346,700,139
March	107,187,992	254,150,400	361,338,392
April	123,824,874	249,607,680	373,432,554
May	141,874,159	246,863,680	388,737,839
June	160,315,973	239,265,600	399,581,573
July	168,276,017	232,863,680	401,139,697
August	170,640,678	222,295,360	392,936,038
September	168,881,881	218,415,680	387,297,561
October	148,793,714	210,472,640	359,266,354
November	139,261,914	198,065,280	339,327,194
December 1		193,155,140

In order to perpetuate the business of Camp Bird Limited the directors, in 1909, took an option on the Santa Gertrudis mine at Pachuca, Mexico. This option was taken up. The Santa Gertrudis Co. was registered on December 31, 1909, with a capital of 1,275,000 shares of £1 each. The holding of Camp Bird Limited in the Santa Gertrudis Co., Limited is 1,155,815 shares. W. J. Cox was appointed advisory engineer to the Santa Gertrudis Co. A report states that recent development in the Santa Gertrudis has cut the vein on the eighteenth level, where the vein is 16 ft. wide, of which 8 ft. assays to the value of $20 gold. A new mill of 600 tons daily capacity is being built.

REMOVING AIR FROM SUCTION AND PRESSURE LINES

By Oskar Nagel

The removal of air from pockets in suction and pressure lines is an important problem, especially in cases where the pipe lines, on account of obstruction, have to be carried up and down. An excellent appliance for removing such air is the Koerting water-jet primer (Fig. 1), which

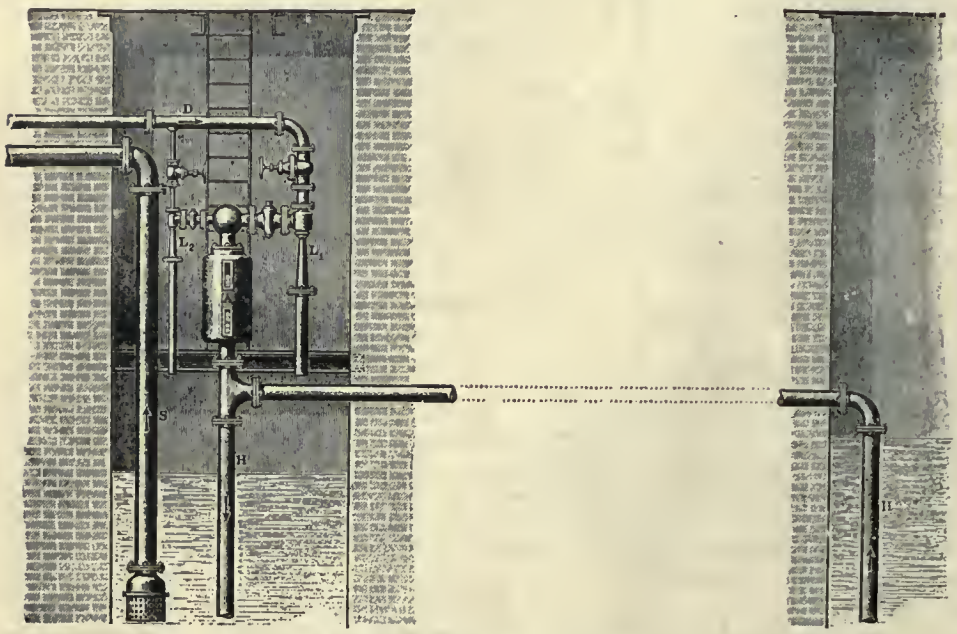

Fig. 1. Koerting Water-Jet Primer.

is successfully used for priming siphon pipes, centrifugal pumps, and long suction pipes of piston pumps. In the cut shown, A is the air vessel, D the water-pressure pipe, H the siphon pipe, and L_1 and L_2 the water-jet primers. As water is always at disposal, in pumping stations the application of these primers is a very convenient matter. They

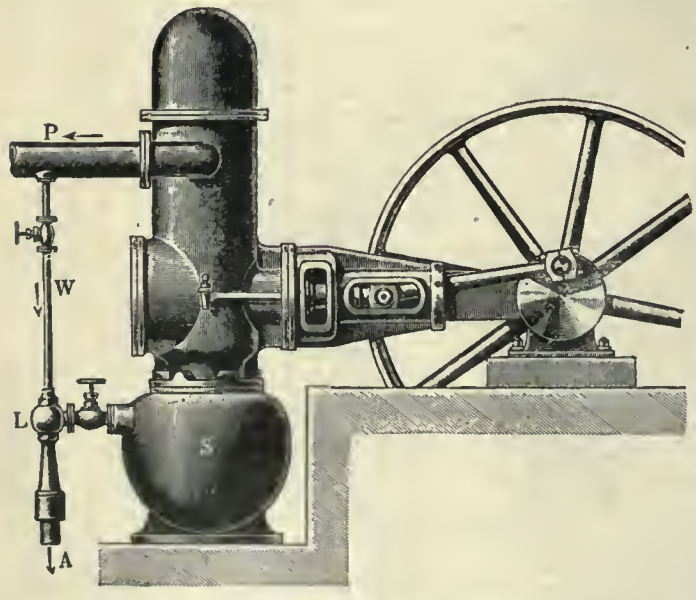

Fig. 2. Exhauster and Engine.

should be placed at the highest point in the piping, which has to be evacuated and one or more exhausters connected to the primer. When using two instruments they should be of different capacities, the larger one being used to fill the pipe-line or system when starting, and the smaller one for continuously evacuating the air vessel which is equipped with indicator-glass to show the rising and falling of the water-level. If the volume of the system to be evacuated is not large, usually only one exhauster is used for filling as well as for continuously evacuating. In such cases the evacuating is done intermittently, and it is advisable to make the air vessel large enough. Fig. 2 shows the exhauster connected to the engine. L is the water-jet primer, P the pressure pipe, S the suction air vessel, and W the water-pressure pipe for primer.

These primers work satisfactorily when only using 30-ft. water-pressure, and they overcome a suction up to 25 ft. The instruments have to be installed always at the highest place. When installed with a centrifugal pump, the discharge pipe of the centrifugal pump has to be equipped with a gate-valve which can be closed vacuum-tight to enable the apparatus to form a vacuum. To start, open the water-valve and then air-cock; to stop, reverse the above operation. When using water-pressure under 60 ft., the discharge pipes of the primers have to be water-sealed. An automatic water-jet primer is also frequently used. The jet apparatus is installed inside of the vessel, and the pressure water is started automatically by a float when the water level falls, evacuating until the water has risen to the proper height; then the water supply is shut off automatically by means of a float-actuated water-pressure valve.

In this connection, a few words on air-valves may be of interest. The Schutte automatic relief-valve is available for air-bound water mains. This valve will open and admit air when a break occurs in the main, so that the water will discharge freely, and it will discharge the air when under pressure, and close as soon as water reaches the float. The floats are made solid, respectively of aluminum and lead, so that the valve is suitable for any pressure.

COMMERCIAL PARAGRAPHS

The Jeanesville Iron Works Co. calls attention to an error in its advertisement on the front cover of the *Mining and Scientific Press* of December 3. This advertisement describes a 5-inch six-stage Jeanesville turbine pump having a capacity of 700 gal. per minute, while the illustration accompanying the same shows a 15-inch four-stage Jeanesville turbine pump having a capacity of 4200 gal. per minute. No blame is attached to the publication for this error, copy having been followed exactly. The 5-inch six-stage Jeanesville turbine pump which is described will be illustrated in the Jeanesville advertisement to appear on page 26 of the *Mining and Scientific Press* of January 7.

The Union Iron Works Co., San Francisco, will on January 1, 1911, move its city office from 320 Market street to the Insurance building at the corner of Battery and California streets. P. C. Jurs is manager of the mining machinery department.

The Revere Rubber Co., of Boston, through its New York store, has been awarded the contract for the suction hose to be used by the Government in raising the battleship *Maine*, in Havana Harbor. The award, coming after a keen competition, is naturally looked upon with considerable pride.

The Westinghouse Diary for 1911 is out. It is issued by the Westinghouse Electric & Mfg. Co., and is the same neat vest pocket memorandum and collection of useful informations as were the previous editions.

TABLE OF CONTENTS

EDITORIAL

TIN is now being produced on a commercial scale near El Paso, Texas, as related in our news columns. It is to be hoped that continued development will show the orebodies there to be large and persistent.

FIFTY YEARS AGO, when J. D. Whitney was candidate for the position of State Geologist of California, a cynical friend wrote him: "Keep your honesty out of sight or you are a gone coon." There have been times since when candidates for the position of State Mineralogist might have taken this advice seriously, but not so now. We are glad to believe that the appointment about to be made to this important position will be well considered, and we hope a good man may be chosen. A number of excellent suggestions have been made. Among those mentioned are Messrs. Ross E. Browne, W. C. Mendenhall, W. H. Storms, E. H. Benjamin, R. P. McLaughlin, P. C. DuBois, W. B. Winston, and others. From this list it should be possible to outfit several bureaus excellently.

SMELTING has been resumed at the Coram, California, plant of the Balaklala Consolidated Copper Company, where the Cottrell process of fume precipitation is on trial. Various difficulties have naturally been found in starting the plant, and the farmers, becoming impatient, recently forced the closing down of the furnace. At that time approximately 90 per cent of the solid matter in the smoke was being precipitated and good progress in experimental work was being made. New electrodes have now been put in and one furnace was blown in December 28. In the Cottrell process an electric current of extremely high voltage is used, and it is not easy to secure an even distribution of current. With better knowledge of insulating material and more experience in operation, it is altogether likely that complete success will reward the efforts of the engineers in charge. Much has already been accomplished.

DUST in the mines and in dry-crushing plants is not only a nuisance, but often a source of danger. In coal mines and in flour mills disastrous explosions have resulted from its presence. Rock dust does not involve this danger, but it is injurious to health and destructive to machinery. In our Kalgoorlie letter of December 17 was a report on a recent investigation of the effect of dust on the health of men underground. Unfortunately corresponding studies of dust in dry-crushing plants seem not to have been made. Relatively few plants have

been equipped with machinery for drawing off and settling such dust, and many mills are constantly full of a regular fog of fine rock particles. One of the Leadville mills has the crushing machinery housed in with sheet iron and by means of exhaust fans draws the fine dust to a settling chamber. Doubtless a number of different schemes have been tried, but there is a surprising lack of definite information on the subject. Engineers having experience in building such equipment would do their fellows a service by publishing plans that have proved effective.

RIGHT TO LATERAL SUPPORT of the ground in its natural condition is generally recognized, though in California and some other States this does not extend to support of improvements. The matter recently came up in an interesting way at Otago, New Zealand, in connection with dredging. It is clear that where different companies are dredging adjacent lots considerable ground would be lost if each dredged only up to the point where the surface would remain unbroken along the line. In the case of the Molyneux Hydraulic Dredging Company *v.* the Karaunui Dredging Company, reported in *The Australian Mining Standard*, the ground in dispute amounted to 3½ acres; enough to keep the dredge in question at work for an entire year. It was decided that the right to lateral support was paramount, and in absence of agreement between the companies, the natural batter of the ground must be maintained. In California the question has not arisen because it is customary for two companies by agreement to each work up to the line on the bottom of the pit for half of the distance along the boundary.

The Eight-Hour Law

When the eight-hour law was proposed, various arguments, pro and con, were advanced. Its friends claimed that miners and millmen were being overworked and could no longer endure the strain; that if given the opportunity the men could, and would, do as much in eight hours as they had been accustomed to accomplish in ten. Its opponents declared that the law would result in a direct increase of expense, which in some cases would be prohibitory, that the men would do no more work in an eight-hour shift than they did in eight of the usual ten, and that in some instances they could not possibly do as much. In drilling with machines, for instance, it was contended that it would take as much time to reach the working place and to set up the machines under one schedule as under the other, and that when a round was to be finished and the machines taken down within the eight-hour period, loss of effective working time was inevitable. In mills, smelters, and at hoists an extra crew would be required and expense increased proportionally. The eight-hour law has now been in force for some time in several mining States, and although not much has been said by either side to the controversy, it would be interesting to know whether it has been as satisfactory to the miners as they anticipated. There are many mines rich enough to bear the increased expense of the eight-hour day, but there are those which, already operating on a narrow margin, were unable to continue work without direct loss when the eight-hour day was imposed by legislative act. These mines were closed after making a trial under the new conditions. It was found that the men, contrary to their prediction, failed to accomplish any more in eight hours than they had previously accomplished in the same length of time, and under some conditions they actually did less. Increase of surface force directly increased cost of operation with no compensating advantage whatever, and nothing remained but the choice of closing down or continuing at a loss, with the decision almost invariably in favor of the former, thus forcing men out of work who had been employed steadily for years under conditions which even they admit were not unsatisfactory.

Suppressing a Government Report

Comment on the Utah Consoldiated collapse has been widespread, and much of it beside the point. Essentially the matter simmers down to a difference of opinion between engineers as to how much ore can be recovered from certain old workings. As to the amount and value of the ore that can now be sampled and measured, there is a slight but not important disagreement. The ore that is in the form of pillars, and which was sampled before the stopes were filled, is admittedly large in amount. Just what value is to be assigned to it, the engineers do not agree. In Mr. J. W. Finch's report of last February the two sorts of ore were discriminated, and the estimates made at that time should not have deceived anyone. Since metals are now selling at a lower rate and some ore has been mined, the reserve must be figured at less than he and Mr. J. B. Risque then estimated it. This correction should be easily made and ought not be large. What further correction, if any, should be made for real or supposed inability to recover the pillars, is properly a matter for difference of opinion among engineers familiar with the property. Any estimate of the value of the now inaccessible pillars and blocks of ore is necessarily based upon records of sampling and assaying at the time the stopes were open. Provided that this be clearly stated, and we understand that both Mr. Risque and Mr. Finch so safeguarded themselves, we see no harm in that. To allow nothing for these blocks of ore would be unfair to the property and would fail to safeguard the interests of the individual stockholder. It is as important to know the possibilities of a property, so long as they are reasonably well grounded, as to know the proved facts.

An example of comment that, in our judgment, is harmful is an article appearing in *Mines and Methods* for December. This article contains nothing new with regard to the particular case in point. Instead it opens with a recital of the details of the famous Emma scandal of years ago and follows with the assertion that the case of the Utah Consolidated is similar. After this is a general attack on the Utah

Consolidated, the United States Mining Company, Mr. A. F. Holden, and the United States Geological Survey. We fear our neighbor by the salty lake has indulged in muck-raking until it has become a habit. We have no desire to belittle honest criticism either of company affairs or technical performance, though for our own part we prefer to cling rather closely to the technical field, and generally leave to others the discussion of financial matters connected with mining. In the present case there is one criticism in particular that we can not allow to go unchallenged. The implication is made that the long delay in publication of the United States Geological Survey report on the Bingham district was due to pressure exerted by or for the two companies mentioned. In the one case the object to be gained was the unloading of stock at high prices before the Survey maps should show that faulting precluded hope of extension of the orebodies. In the other it is suggested that, if the report had been promptly published, it would have been impossible for the "very extraordinary" and "seemingly absurd" claim of the United States company to the Kempton orebody to have been allowed by the court. The editor attempts to exonerate Mr. J. M. Boutwell and Mr. S. F. Emmons personally, but "submits that the suppression of the report demands a rigid investigation by the head of the department." This, we are sure, Mr. George Otis Smith, the Director of the Survey, will be glad to make if there be any evidence of "suppression." The report was delayed, it is true, but not to further private interests. From a long and intimate association with the United States Geological Survey we can state without fear of contradiction, that no one has influence enough to secure the suppression of a report by that Bureau. It has been customary, as is, we believe, entirely proper, when an officer undertakes the study of a district in which litigation is in progress, and where the various parties to the suits give him access to all their confidential maps and data, to agree that no publication shall be made until the particular suits pending are settled. Upon no other terms could a mine manager afford to open his files to the Survey geologists, and without the confidence and help of the mine managers the survey would not be worth making. Whether there was such an agreement in this case we are not informed. If there was, it was proper that the report should be delayed until the suit was ended. Our impression is, however, that in this particular case the delay was due to the inherent difficulties in making the survey, to the fact that it was Mr. Boutwell's first important independent assignment, so that he naturally desired to delay publication until he had had the opportunity to test his conclusions at Park City and elsewhere, and to the usual difficulties in getting any illustrated Government report edited and printed promptly. The last mentioned cause is sufficient in itself to explain much delay. Having suffered from it both as author and reader we feel that to do justice to the subject requires more time and space than is now available. For the present it is sufficient to say that no one need be under any misapprehension. It is impossible to suppress a Government report, though to get it promptly published is difficult.

New York Stock Market

The general situation in the East remains unchanged. In truth, it is this fact that gives Wall Street cause for bitter complaint. The leaders in the financial district have insisted upon looking on conditions as temporary, though the real disturbing element is, that so far as market operations and activity are concerned, no turning point is in sight; nothing will induce the public to buy. Brokers have been taking small profits from one another until resources in this direction are about exhausted. The curb market has become much demoralized, so much so, that the really important traders are seeking some means of coming under the protection of the larger exchange so as to establish a legitimate commission charge and protect the market against bucket-shop methods, get-rich-quick schemes, and irresponsible traders. The growing importance of the mining securities market and the demoralization of the curb in the matter of commissions and in the reliability of the traders and brokers, has resulted in a large number of the more important mining companies seeking to be admitted to the New York Stock Exchange. Mines Company of America, Chino, and Ray Consolidated are soon to be listed. Tuolumne is to be listed on the Boston Stock Exchange. The stock exchange authorities have unofficially suggested that any of the mining companies able to formulate reports and properly make application for trading privileges, should do so without delay. This move means not only that the outside market has lost the confidence of the public, but also that the officers of the stock exchange have at last unwillingly awakened to the necessity of recognizing mining issues and the public trading in them. Back of this is the further fact that the various restrictions and safeguards being now built up around the railway securities in the form of the Commerce Court, the Inter-State Commerce Commission, and the various State public service commissions, are gradually hedging in the field of railway finance, and while adding greatly to the attractiveness of railway shares as investments, are at the same time eliminating speculative possibilities. It has become necessary to seek some other securities to attract the speculator. If the bars are let down so far that it will be possible for a mining company to secure admission to the Stock Exchange before the mine is out of the speculative stage, trading in these securities should become an important part of the business on the floor. Such development will be altogether to the benefit of the mining industry. Heretofore, mining shares have always been scorned by the members of the New York Stock Exchange and by the New York banks, and such issues as gained admittance have found a forbidding atmosphere in which all activity quickly languished. Even Goldfield Consolidated, when removed from the outside market to the big board, lost a large part of its activity. Trading in this issue now marks a steady campaign of distribution.

The Clancy Process

By J. C. Clancy

*The Clancy process is designed especially for the treatment of refractory ores, in which the gold is associated with chemical compounds and is not susceptible to the action of solvents until the ore has been roasted, or until the gold has been disassociated from the chemical combination by some other method of oxidation. A long search for a suitable solvent for such ores, led, after repeated disappointment, to discovery that urea, in conjunction with cyanate, and electrolysis of the solution, dissolved gold leaf. The next question was, would any similarly constituted organic compound do the same thing. Urea being an amide compound (carbamide), I thought at once of cyanamide. I thereupon added a solution of cyanamide (using the calcium cyanamide of commerce which is soluble to the extent of about 58 to 65% in water) to a cyanate solution, electrolized it, tested the solution as before with gold leaf, and dissolution of the gold took place in a few minutes. With a view to studying this peculiar reaction, I tried electrolysis on a solution of calcium cyanamide, without any admixture other than the addition of a little alkali to increase the conductivity. After electrolizing for ten minutes at a fairly high current density, the solution dissolved gold leaf in about fifteen minutes; this solution also gave a substantial titration with silver nitrate, showing probably that cyanide had formed. Again, treating the original solution with the addition of potassium thiosulphate and boiling, for the purpose of converting any cyanide present into sulphocyanide, on testing this solution with ferric chloride it gave the characteristic blood-red coloration of the iron sulphocyanide—surely ample verification. To make it more confirmatory, I added a solution of ferrous sulphate, to convert any cyanide in the solution into ferrocyanide. On addition of ferric chloride it gave, on boiling, the characteristic prussian blue. I was satisfied that some cyanide was formed by the electrolysis of calcium cyanamide, but as to the amount produced from a given quantity of cyanamide I was in the dark, owing to the peculiar behavior of the titrating solution in presence of organic compounds. It seemed from different experiments made, that the production of cyanide by electrolysis of cyanamide solution, was frequently below three to four-tenths of a pound KCN per ton of solution. During all these tests I used solutions analogous in strength to working solutions. On referring to Ward's 'Dictionary of Chemistry,' page 314, line 65, Vol. 2, I found that cyanamide combines with potassium cyanate to form mono-potassium amidodicyanate, whose formula is $(CN)_2NH_2OK_2$. Reflecting on this reaction, I thought it probable that, as the cyanide was formed by the electrolysis of the cyanamide, it was oxidized by the current to cyanate, the cyanate then acting upon the unaltered cyanamide to form potassium amidodicyanate. Potassium amidodicyanate when electrolized forms a powerful gold solvent, although it does not give any appreciable reaction on titration with silver nitrate. I have many notebooks filled with interesting data in regard to these reactions, and propose later to publish the results. I may state, however, that when a solution of calcium cyanamide is mixed with a solution of alkaline ferro-cyanide and allowed to stand for a few hours, and even after weeks' standing, it becomes an active solvent for gold without the aid of electrolysis, and when applied to the treatment of ores amenable to straight cyanidation, gives results, equivalent to the simple cyanide treatment, even in very dilute solutions. Further, this process can be used on ores which have already been treated by the cyanide process, that is to say, on residues. There exists in dumps a large proportion of prussian blue, which when treated with alkali becomes in substance, potassium ferro-cyanide and ferri-cyanide, or soluble prussiates.

This opens up a cheap means of treating ores amenable to the ordinary cyanide process as well as ores—residues—which have already been treated by the cyanide solution, that is to say, ores from which the precious metals have not been wholly extracted, and which would not pay for re-treatment by the ordinary cyanide process on account of the cost of cyanide. The following is an example of using this process upon ore amenable to cyanide treatment: Make a solution consisting of 2000 lb. of water containing one pound of calcium cyanamide, one pound of alkaline ferro-cyanide, one pound of lime. The ore is subjected to this solution in the ordinary way, in proportion of two parts of solution to one part of ore, for a period of say 8 to 10 hr., or until extraction is complete. The following is an example of using the process upon ore which has already been treated by the cyanide process and exposed to atmospheric oxygen which occasions the formation of prussian blue and other ferro-cyanogen compounds. The ore when treated with a solution containing one pound of cyanamide, one to five pounds of lime (the amount of lime of course depending upon the acidity of the ore), in 2000 lb. of water, gave results equivalent to the use of straight cyanide solution when used in the proportion of two or three parts of solution to one part of ore. Again, if the above mixture be electrolized the solution of the gold is extremely rapid. Calcium cyanamide mixed with alkaline sulpho-cyanide, electrolized, immediately becomes cyanide and dissolves gold rapidly. Another amide compound, guanidine carbonate, mixed with potassium cyanate, in conjunction with electrolysis of the solution, dissolves gold leaf in less than ten minutes. I might cite a long list of amidogen compounds in conjunction with cyanate solution if space would permit.

In the midst of this work on cyanogen-bearing materials the thought occurred to me to try the combination of calcium cyanamide and iodine. I forthwith made a solution of calcium cyanamide, adding a solution of iodine, to see if this combination would dissolve tellurium, and was rewarded by finding it to be an excellent solvent. I next tried gold leaf

*Abstract of a paper presented before the American Electrochemical Society, December 16, 1910.

with the same combination and had the satisfaction of seeing the gold undergo dissolution in a short time, a scum of calcium carbonate which forms on the surface preventing more rapid dissolution. From this I deduced that the addition of iodine formed cyanamidogen iodide. I am unable to find any reference to this compound in chemical literature which I have read, and I, therefore, take the liberty of calling it by the above name, and further assume the formula to be CN_2I_2. I next tried the action of cyanogen iodide upon a solution of calcium cyanamide, knowing that cyanogen iodide would be destroyed by an excess of alkali, and anticipating that this combination would dissolve telluride of gold. Upon applying the solution to tellurium and telluride of gold, these substances at once dissolved, showing that the dissolution was probably due to cyanamidogen iodide, and I again presume the reaction to be in accordance with the formula

$$2ICN + CaCN_2 = Ca(CN)_2 + I_2CN_2$$

I will now describe the general method of using the Clancy process on the working scale. The ore is crushed by stamps, rolls, ball-mills, or any other efficient form of preliminary grinding mill. The degree of fineness necessary for the process being about 100 mesh, this is probably most economically accomplished by the use of tube-mills. The ore is crushed in a cyanide solution containing calcium cyanamide, sulphocyanide, and the halogen salts. It is, therefore, under the influence of straight cyanide treatment practically after leaving the rock-breakers and until it reaches the agitation tank, where it meets with electrolysis, which acts upon the cyanide solution containing the additional chemicals, and these, under the action of electrolysis, forms powerful solvents for the precious metals, as already explained. Before describing the treatment solution, the manner of dissolving the cyanamide should be known. Calcium cyanamide of commerce comes as a black powder and is about from 58 to 65% soluble in water. It is necessary, therefore, to dissolve the cyanamide in a separate tank and filter it from its insoluble residue. A small air-agitating tank is admirably suited to this purpose, and at the same time it will act as a cyanamide storage tank. The cyanamide solution may be made as highly saturated as desired, and the calculated quantity drawn off when required, and added to the cyanogen-bearing solution. The treatment solution is made up to 2000 lb. water, containing 1 lb. of cyanide, 2 lb. of alkaline sulphocyanide, 2 lb. of calcium cyanamide, and ½ lb. alkaline iodine. If using crushing rolls after the rock-breakers, the product leaving the rolls at about 12 mesh is fed into the tube-mill and converted into pulp, by feeding the mill with the treatment solution and ore, in the proportion of one part of ore to one part of solution. The discharged pulp, after separation of the oversize, is transferred to the agitation tank to undergo electrical treatment. If it is thought necessary to remove the sulphides before, after, or during the treatment, the following method presents an ideal scheme. When solution with finely divided ore in suspension contained in the well-known cone-shaped tank in the proportion of 2 of solution to 1 of ore, or in the proportion of 3 of solution to 1 of ore, is agitated, if the agitation be stopped for a few minutes, the finely divided sulphide particles settle to the bottom of the cone, and by simply opening the discharge valve at the cone apex, the sulphide may be completely drawn off, together with a small proportion of the non-sulphide pulp. This sulphide product may be run over blankets, or some similar contrivance, and the finely divided concentrate collected, the excess of pulp solution being returned to the agitation tank for treatment. Here is a means of eliminating the use of concentrating tables and obtaining a product of high value in small bulk. Again, the pulp being in a finely divided state, the pyrite or sulphide portion is not accompanied with quartz or gangue; therefore, a clean high-grade concentrate is obtained, a result that can not be accomplished by the use of concentrating tables, without the employment of a large quantity of solution with attendant expenses. The pulp now in the agitating tank is of the correct alkalinity, this being previously established in the tube-mill by adding lime so as to contain from $^1/_{10}$ to $^2/_{10}$ of a pound 'protective' alkalinity per ton of solution.

The conductivity of the pulp is adjusted by adding common salt until the required voltage is obtained; 20 lb. of salt per ton of solution will invariably decrease the resistance of the pulp so that the volt motor will register about from 5 to 6 volts. In the majority of cases a current of about 50 amperes per ton of ore is adequate. It will be easily seen that the cost for electrical energy is not by any means prohibitive. With iron-oxide electrodes it is possible to obtain a current density considerably over 50 amperes per square foot of anode surface, so that one electrode 3 ft. long by 3 in. diam. will be sufficient for the treatment of from 3 to 4 tons of ore; in other words, approximately 30 of these iron-oxide electrodes would be required for the treatment of 100 tons of ore per day. If the treatment tank be constructed of iron the tank itself may be used as the cathode. This arrangement would, of course, decrease considerably the cost of installation. The electric generator is the chief item of cost. A low voltage generator, such as a 10-volt machine capable of giving the necessary amperage, can be obtained at any of the electrical warehouses. It is obvious, therefore, that the process may be applied to any existing fine-grinding plant provided with agitating tanks. All that is necessary, is simply to introduce the electrodes into the circulating ore pulp containing the necessary chemicals and switch on the current. It is essential in every case to maintain the protective alkalinity at about $^1/_{10}$ of a pound alkali per ton of solution so as to allow of the formation of cyanogen iodide and cyanamidogen iodide. About eight hours' treatment under electrolysis usually is sufficient to obtain the necessary extraction.

After the eight hours' treatment with the current, the pulp solution is brought up to about one pound per ton of protective alkalinity by adding caustic soda, and the cyanide contents regenerated up to about $^5/_{10}$ to $^6/_{10}$ of a pound cyanide per ton of solution. The regeneration of the cyanide is then ac-

complished simply by giving the pulp about two hours more current. It will be understood that the reason for adding the extra alkali is, that cyanide regeneration cannot take place in the presence of a halogen compound unless the solution containing sulphocyanides and cyanamide is made alkaline. It will be seen that the whole value of the process depends upon the recovery of the halogen compound. While I have described in the examples a proportion of two parts of solution to one part of ore, a proportion of three parts of solution to one part of ore may be used with advantage, that is to say, by using three parts of solution to one part of ore, a much smaller amount of alkaline haloid may be used per ton of solution; thus giving the same ratio of haloid salt per ton of ore as in the two of solution to one of ore pulp, and consequently a less proportion of soluble haloid to be displaced by the water wash in the final slime cake.

In this necessarily comparatively brief and incomplete description of the process, the use of chemicals and current have been described, but no mention of costs has been made. I will, therefore, take the following example to represent the typical working solution: 2000 lb. of water containing 1 lb. of cyanide, 2 lb. of sulphocyanide, 2 lb. of calcium cyanamide, and ¼ lb. alkaline iodide. This appears a formidable mixture when looked at cursorily, but on analysis it does not work out beyond the limits of economic treatment. For example:

Lb.	Substance.	Cents.
1	cyanide	18
2	cyanamide	6
2	alkaline sulphocyanide	12
¼	alkaline iodide	35
	Total	71

This would not represent the total cost of one ton of solution, for, notwithstanding the effect of electrolysis, practically all the haloid salt, or salts, previously added, together with the sulphocyanide will be found unimpaired at the end of the operation, the cyanide and cyanamide alone suffering the necessary decomposition. It is clear, therefore, that no matter what the proportion of solution to ore, only the consumption of cyanide and cyanamide per ton of ore is to be taken into account. The amount of cyanide consumption on the ore, in presence of cyanamide, works out at about 1 lb. of cyanide per ton of ore treated. This consumption of cyanide is regenerated at the expense of 3c. for cyanamide, and at the outside 3c. for current (figuring current at 1c. per kilowatt hour), making a total cost of 6c. per ton of ore. Added to the above cost is the cost of the electrical energy necessary for the electrolysis of the ore pulp. The cost of electrical energy for this purpose works out at about 10c. per ton of ore treated, this added to the cost for cyanogen-bearing material and regeneration, would make a total of 16c. per ton of ore. These figures would represent the total cost, provided that all the solutions were recovered without mechanical loss. From this it is evident that the recovery of the solutions for re-use is a matter of vital importance to this process. The mechanical recovery of the solutions is, therefore, entirely dependent upon the efficiency of the filter employed. The Moore filter eminently fulfils the requirements for the recovery of the solution, inasmuch as it gives perfect uniformity of cake, both in thickness and porosity, which means perfect resistance, and perfect resistance guarantees perfect displacement. In fact, the business combination of the Moore filter with the Clancy process was originally brought about, not from any arbitrary or usual business considerations, but because, after the most rigid examination of all existing filter processes, I learned in my demonstrations that this type of filter was the only one that could be depended on to recover practically all of the solutions. This filter process is too well known to describe minutely. Suffice it to say, when the final step in the cycle of treatment is reached, that is, when the cake has been washed with barren solution, the soluble salts contained in the moisture saturating the cake at this juncture, may be completely recovered by giving the cake the requisite amount of water for displacement. The necessary amount of water for displacement is readily seen without calculation by the diminution of the water level in the wash tank. It has been necessary to mention the unique points of this filter so as to show how the solutions can be recovered with a minimum of mechanical loss and with a minimum of water wash. In a properly constructed Moore filter (type A), the loss of solution under proper manipulation should not exceed 10% of the total solution. It should be understood that the above costs are based on the treatment of rebellious or refractory ores and that they would in all probability be much reduced when dealing with non-rebellious ores.

WATER POWERS

There is now withdrawn from disposition, pending legislation concerning water-power sites, approximately 1,450,000 acres of the public domain. In regard to them the Secretary of the Interior in his recent report says: "In the various public-land States and Territories containing water-power resources, in so far as there is present market for those powers, the title to areas greater in extent than that remaining in the Government has long since passed into private ownership, and it must be realized that any radical or burdensome restriction imposed by the Federal Government upon this resource will operate as a servitude on the public lands and discourage their development and use. Taking into consideration the facts that the States own the waters in the streams and have police power to supervise and control public utilities, it would seem a direct and effective method of control would be to trustee the power sites to the States in some such manner as proposed by a bill now pending in Congress. I earnestly advise the adoption of some legislation which will in any event retain the fee title to the lands in the people and effectually vest the power of regulation and control in the State or in the Federal Government, and which will not result in limiting prompt and economical development or permit monopolization or extortion."

Mining in the San Juan—III

By William H. Storms

Six miles above Ouray the new Camp Bird mill is situated, near the bottom of the east fork of Canyon creek, a hundred yards or more from a precipitous bluff over which the creek falls in a series of cascades. The mill which formerly stood on this site was destroyed by a snowslide in the spring of 1906, when two slides, one from each side of the canyon, rushed down the mountain-sides back of the mill, and uniting in one huge pile of ice and snow, rolled over the cliff and swept away the greater part of the mill structure. A day or two later, from some unknown cause, the débris caught fire and burned, adding to the scene of devastation, but aiding somewhat in clearing away the wreck previously wrought by the snowslide. The site of the Camp Bird mill is at about 9100 ft. above sea-level. Since the snowslide, precautionary measures have been taken to prevent, as far as possible, a repetition of the disaster of 1906, by the construction of rock walls and other structures in the usual path of the snowslides. These have been found to be of much benefit, as they appear to have the effect of preventing the slides from starting, or, at any rate, in keeping the accumulated snow from coming down all in a single slide. Under all ordinary conditions the Camp Bird mill seems to be in no danger from snowslides at any time, but the experience of the past has taught the dwellers of the San Juan to distrust appearances, at least as far as snowslides are concerned.

The new Camp Bird mill was erected on the site of the one destroyed by the snowslide of 1906. It is connected with the Camp Bird mine by a Bleichert tramway two miles in length. The ore is delivered at the top of the mill, where the buckets are detached from the cable and pushed by hand along a horizontal track suspended over the grizzlies. A short section of this horizontal track is con-

nected by a system of levers with a scale, and here each bucket of ore is stopped and weighed as it arrives, by the trammer, and the weight registered, so there is no guess-work about the quantity of ore going to the stamps daily. This, in my opinion, is a device which many other mills, not only in the San Juan, but elsewhere, might introduce to advantage. Four rock-breakers of the Blake type crush the ore to a size suitable for the stamps. The bins beneath the grizzlies and breakers have a capacity of about 1000 tons. They have been built with sloping bottoms and are of substantial construction. From the bins the ore passes to the suspended automatic feeders and thence to the stamps, 60 in number, each weighing when newly shod 1050 lb. They drop 7 inches 100 times per minute. The screens used are the double-crimp, 26-mesh, 29-wire, of the Ludlow-Saylor company. These have been found to give satisfactory results and service. These screens are placed in the mortar front in vertical position and not inclined outward at the top in the customary manner.

There are a number of things in the Camp Bird mill, and in the metallurgical practice, that are unusual, and consequently deserving of notice, particularly as these innovations appear to be perfectly satisfactory to the management. The exact weighing of the ore as it arrives at the mill, was the first thing out of the ordinary, to attract my attention. The vertical setting of the battery-screens was next. The third was the unusual position of the line-shaft, which I found to be directly in front of the mortar-blocks and beneath the amalgamating tables. This line-shaft has been made by uniting, by means of flange-collars, old cam-shafts from the wrecked mill, and which have been found to answer the new purpose to which they have been put most admirably. The mortars each weigh 7000 lb., and rest on 7-ton anvil blocks, which are solidly bolted to heavy concrete foundations. The battery-posts stand on streak-sills that are bedded on the concrete of the foundations.

From the mortars the pulp passes to a 24-ft. run of silvered copper amalgamating plates 4 ft. wide. From these plates the pulp goes by short launder to revolving mercury traps, one to each five stamps. In these traps is recovered a large amount of quicksilver and amalgam. I had heard that at the Camp Bird mill the sand went to belt machines and the slime to Wilfleys. This I knew to be contrary to common practice, to say the least, but current report was, as usual, inexact. However, I did find another innovation. From the mercury traps the pulp goes, without classification, to 6-ft. vanners of the Frue type—two to each battery of 5 stamps, as the ore carries a variable though large percentage of sulphides and, unfortunately, also other minerals of high specific gravity, but which are of no economic value. From the vanners the tailing goes to a large spitzkasten, the sand from which is sent to Huntington mills in which it is re-ground to 40 mesh, with a minimum of sliming. This re-ground material is again passed over amalgamating plates and from these goes by launder to the cyanide plant. The middling from the classifier goes to 11 Wilfley tables, and the overflow to the cyanide plant direct. T. H. Woods, the mill superintendent, told me that the material sent to the Wilfley tables contained the greater part of the rhodonite (manganese silicate), which is more or less abundant in the Camp Bird ores, and that by this means he was able to eliminate a great part of it. He further stated that he considered it objectionable in the cyanide tanks. None of the other mill superintendents in this vicinity, nor at Telluride, seemed to have found rhodonite harmful or objectionable. However, this is not so strange, when it is considered that the metallurgical practice in the various mills of the San Juan region is entirely dissimilar—no two mills employing the same process, even when situated side by side as at Telluride. In fact, the mill practice in the several mills is as unlike as though the mines were a thousand miles apart.

The cyanide department of the Camp Bird is in charge of A. C. Bricker. The mill is provided with both water and electric power. The water is under a head of 340 ft., but the available volume is variable. It is utilized as far as possible, electricity supplying the deficiency. The mills are heated by steam, and solutions are kept at about 55 degrees throughout the year.

Low Mortars and High Heads

By M. P. Boss

The gravity-stamp is a mechanism of simple construction and its wearing parts are easily renewable. The regularly recurring drop of stamps in action generates vibration of the foundation and framework, which is the one trying element of construction. An individual blow from a stamp creates but small square-inch pressure at the bottom of the mortar, but the rhythmic recurrence of drops vibrates even the earth upon which it stands, sometimes noticeable hundreds of feet underground. There are two sources from which this vibration is generated; first, from the cam-shaft in picking up the stamps, and second, from the mortar that receives the blows. Low and flat foundations are better for minimizing vibration than high pedestals.

The vibration in the stem of the stamp is distinct from, and independent of, the vibration in the foundations of the battery. The material upon which a stamp falls is uneven in size and is not evenly distributed over the die, so that the arrest of the blow will usually be mostly away from the axial centre of the stamp, which will give a lateral strain or wrench to the stem. The vibrating effect of this strain upon the stem varies with the structural design. A high centre of gravity of the stamp, the lower guide high above the die, and guides wide apart, are factors conducive of vibration. The stems in such a battery construction usually will begin to break after having been about a year in operation.

By making the stamp-head long and the stem not unnecessarily so, thereby bringing the centre of gravity low, and by putting the lower guide as close

to the head as its convenience of operation will admit, the vibration of the stem will be so minimized that breakage is practically eliminated from consideration.

What I look upon as the leading feature in the low mortar, as compared with ordinary mortars, is

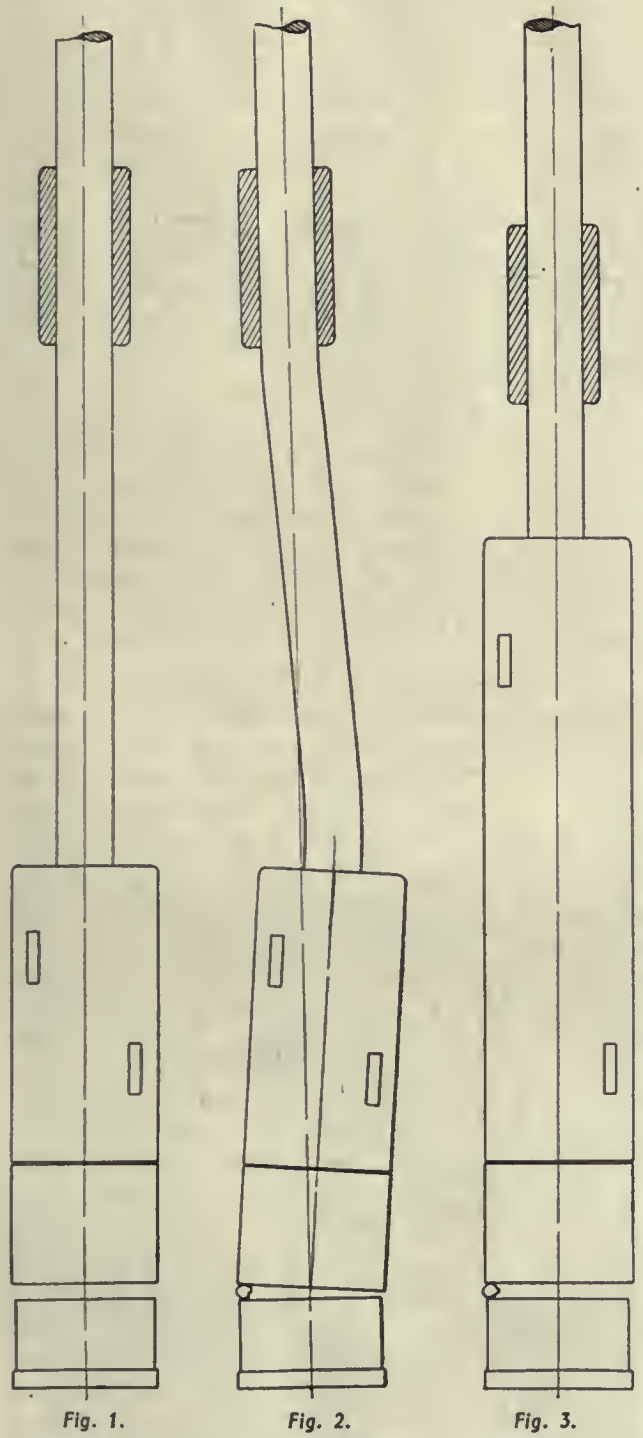

Fig. 1. Fig. 2. Fig. 3.

Fig. 1 shows a stamp of common design and proportions. Fig. 2 is the same stamp, showing (by exaggeration) how the stem is caused to spring. The spring is followed by vibration and continued vibrations cause stem breakages. Fig. 3 shows how stem vibration is so minimized that breakage of stems rarely occurs. A long stamp-head, with the lower guide set low, permits but little spring.

with me an old idea. As far back as when the French company built the 60-stamp mill at Quartz mountain, in Madera county, California, about 1884, I put in low mortars with heads running close to lower guides to minimize stem breakage. The next low mortars I put in were in my own mill at Pachuca, Mexico, which started crushing March 1, 1889. This mill I also built with concrete battery foundations and with iron guides. The latter two ideas the public accepted with a delay of but a few years, but the low mortar has never heretofore become the fashion except where I have personally influenced conclusions, notwithstanding that at our new 30-stamp mill after I incorporated the Hacienda de San Francisco, of Pachuca, of which I was managing director and largest individual owner for more than seven years, there were only four stem breakages. Throughout the years following I have not known or heard of a single stem breakage in all other mills in which I have placed my stamps with low mortars and long heads. During these many years I have heard no tangible objection, or argument, against low mortars and long stamp-heads, but the mining public has continued indifferent. This standard mortar, the plans of which I sent to Africa through Fraser & Chalmers of London, was novel in the peculiar construction of its housing around the stamp-head and in the liners. The front liner is extended upward with an open panel to hold the screen and is held in place by being slid down in a channel and held by a rope caulking. A number of these liners of different heights or modifications may accompany each mortar. The screen is let into the liuer panel to present an approximately flat front to the splash. This front liner also has upon its inner surface inflecting lugs to augment the splashes over the screen. The back liner is shaped to somewhat encompass the dies sufficiently close to facilitate the suction action of the rising stamp. Effective suction of the rising stamp is an important factor in crushing by stamps. The bottom liner has pockets to receive the neck of the dies, such as are shown in Fig. 4.

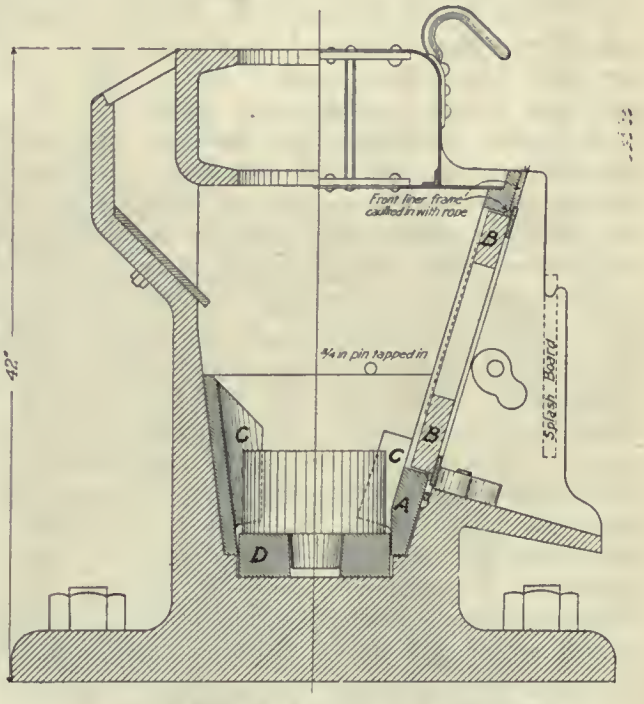

Fig. 4. Low Mortar. A, Front Liner. B, Screen Frame. C, Back and Front Liners Shaped About Die. D, Bottom Liner.

Future of Dredging

By Charles Janin

The future for gold dredging is a matter of growing interest in California and elsewhere. It is the contention of most engineers and operators familiar with the conditions, and is undoubtedly true to a great extent, that the limits of dredging areas in California have already been fairly well defined, and that the greater portion of the field is controlled by the large interests. Other engineers are more optimistic and believe that tracts which have previously been passed over, or reported on unfavorably, when prospected some years ago, still hold possibilities for the future. With the great advance made in the industry and the development of the modern dredge, from the earlier successful boats with their 600 cu. yd. per day capacity, to the boats with 16-ft. buckets and the estimated capacity of 300,000 cu. yd. per month, and the reduction of working costs, under favorable conditions, to less than 3c. per cu. yd., it is obvious that areas which a few years ago were considered too low grade to equip with a dredge will, under present conditions, again attract the attention of those interested in the dredging industry. Another fact that is drawing attention to these areas, first considered unprofitable, is that the life of some of the successful dredging companies is drawing to a close; that is, the land for the working of which the company was originally formed is being rapidly worked out. Several of these companies are realizing that their ground is nearly exhausted, and that the company has one or more dredges in good condition, fit for some years of working life, so far as the machinery is concerned, and, what is probably more important, a well organized working force, valuable experience in dredging matters, money in the treasury, and the confidence of shareholders. The machinery from dredges that have worked the areas for which they were built, or that have been dismantled and replaced by larger boats, has been overhauled and refitted on new hulls in different fields. Dredges that were at first installed on ground in Colorado which proved unprofitable, were dismantled and the machinery is being used on hulls in California. The machinery from several California dredges has been moved to other fields in California, and in some cases to Alaska. The machinery of a good dredge can be refitted on a new hull and installed on a nearby property, in some cases, at less than 50% of the cost of a new boat, though it must be recognized that these boats may not always be best suited for the most economic handling of low-grade gravel. The salvage in these disused boats, and exigencies of stock manipulation, will without doubt have considerable influence in deciding the management to favor the working of new areas. Aside from such influences, there is no question that under favorable conditions areas that were at first considered unsuitable for economic dredging can now, with improved methods, be profitably handled. The possibilities of reclamation of dredged land may prove a not unimportant item in estimating the profits to be won from dredging areas in California. The success attending the efforts of some operators in this direction has greatly broadened the expectations for the future of what was, until recently, considered worthless land. A more liberal attitude on the part of the agriculturists and arrangements permitting the modification of some of the rulings of the Débris Commission would open areas to the dredging industry that are at present closed. Altogether, it seems probable that there will be opportunities for profitable investment in California dredging for some years to come.

In Alaska there is a growing demand for dredges of the smaller class, having 2½ to 7 cu. ft. buckets, a number of which have been installed in the last year and several of which are planned for 1911. In addition to these smaller boats, the Far North can boast of one of the largest dredges yet constructed, a Marion 16-ft. bucket dredge installed on the Boyle concession in the season of 1910. This boat has a total weight of 900 tons and will dig approximately 10,000 cu. yd. per day. On this same property a Marion 7-ft. bucket boat has been successfully working since 1906 and is still in good condition; for the past season it is said to have averaged 3700 cu. yd. per day.

Besides the possibility for new dredging areas in California, and other Western States and in Alaska, the attention of dredge operators has been attracted to the many opportunities for the installation of dredges in foreign countries. Much interest has been manifested in Siberia of late, and a number of American engineers have been engaged during the past year in the examination of Siberian gravel properties. Most of these engineers went out for English companies which are, perhaps, better able than Americans to cope with some of the disadvantages of operating under Russian authority. For reasons obvious to those familiar with conditions, it will be found advisable in starting new enterprises in that country for Americans, or other foreigners, to have the assistance of, and be associated with, influential Russians. A number, if not all, of these recent examinations of Siberian gravels resulted unfavorably, some on account of the low grade of the gravel, others because of severe business conditions or exorbitant prices imposed by the owners. However, there is no question that, so far as operating conditions are concerned, there are areas of gravel in Siberia that can be profitably worked. A more liberal policy on the part of the owners of some of these tracts may result in dredges being erected in the near future. Recent reports from the dredges operating in Siberia show an increased working efficiency, both in the yardage handled and the percentage of gold recovered per dredge. This is undoubtedly due to better management, the employment of heavier and more modern dredges, and the practical experience gained from operation. Without doubt, the increased success of these boats will stimulate new promotions and will result in further investments being made.

Recent engagements of experienced engineers for

West Africa indicate that it is being more seriously considered as an attractive field for dredging investments. Some of the first dredges there, as in other fields, were failures, but the employment of competent men is the first step toward obtaining reliable knowledge of existing economic conditions, and securing the installation of suitable dredges when they are warranted. This practice, if more often followed, would save investors much money and give a far better tone to the mining business in general.

It may be said that the majority of dredges placed in South America have been unprofitable. This has been due, in part, to a failure to recognize, or to properly appreciate, the difficulties of installing and operating a dredge under the conditions existing in South American countries, and in part to equipping a property with unsuitable dredges on ground, the value of which was optimistically guessed at rather than determined by careful sampling. In other words, the failures in South American fields, as elsewhere, may be attributed to investments being made without proper engineering advice. Notwithstanding the early failures and the consequent disrepute into which South America has fallen in this respect, dredging properties of merit, properly presented, will receive ready consideration from capitalists. Some California engineers have been recently engaged in examinations in Colombia, Brazil, and other South American countries, and several engineers of experience believe that there are excellent opportunities for profitable dredging in these countries. The most important dredging work in South America is that on the property controlled by the Oroville Dredging, Ltd., on the Nichi river, in Colombia. The area was carefully examined by capable engineers, and is probably the first South American property to be drilled and prospected in the systematic manner in which such work is done in California. Over 300 acres were proved to be profitable dredging ground. The company has a concession of 22,000 acres, the greater portion of which has not yet been prospected, and there seems little doubt that other parts of the concession will also be found to contain gravel of workable grade. A hydro-electric plant has been built and an 8½-cu. ft. bucket, California type, dredge, with steel hull, will be built. The success that will follow the efforts of the experienced management of this property will encourage the exploitation of other areas and undoubtedly prove an incentive to other dredge installations in South American fields.

In French Guiana, dredging has been tried so far on three rivers only; the Cureibo, the Sparwin, and the Lizard. Three new dredges are in course of construction in those places, an indication that the first results, either in dredging or in prospecting, have been encouraging. There are in French Guiana other rivers equally rich. According to the latest reports, a new dredge operating in Roche creek, carefully prospected in 1908, has given an output of 8 kg. in March and 10 kg. in April 1910 (1 kg. of this gold is worth about $500). Experiments extending over a period of 6 months were made with an English dredge of 1000 cu. m. (theoretical) capacity a day, but which, owing to difficulties of operation, was unable to wash more than from 300 to 400 cu. m. in 24 hours. These experiments are said to have demonstrated that the cost of operation in handling this amount of gravel was from 36 to 42c. per cu. yd. Operating conditions are likely, however, to improve with further experience. In British Guiana, dredges are successfully operated where the gravel is much lower in gold content than that of French Guiana. It might be that better results could be obtained in French Guiana by employing convict labor, but thus far experiments in this direction have been far from encouraging; another attempt is to be made on a placer near S. Jean du Maroni, the outcome of which will be watched with interest. An entertaining account of the 'Goldfields of French Guiana' by Albert Bordeaux, from which the above paragraph was abstracted, appears in the Trans. Amer. Inst. Min. Eng. for November 1910. In Dutch Guiana, gold dredging has been carried on along the Saramaca and Marowijne rivers with small Holland-built dredges.. It is said that some of these operations are successful and that other installations may soon be made.

In Mexico, several gravel areas have at times attracted attention. A dredge was installed at Suaqui Grande, Sonora, some years ago, but was not a success. Other places in Sonora along the Yaqui river, near Tonichi and San Antonio, were prospected with Keystone drills with indifferent results. A prospecting party is now drilling at the latter place, but reports from it are not encouraging. The dry placers of Altar have been brought into prominence recently by the success of the Quinner 'dry-washing' machine, and it is believed that these will prove of importance. In Sinaloa there are places where it is claimed that the ground could be profitably dredged. It was reported that a dredge was to be installed there some months ago, but nothing definite has since been heard regarding it. Although successful dredges may be installed in the future, the present outlook for gold dredging in Mexico is not brilliant.

Among other fields that may be mentioned as offering possibilities for gold dredging are Korea, China, and the Philippine Islands. In Korea tests have been made of gravel areas and it has recently been reported that a dredge is to be erected. In China there has been no dredging, but engineers consider that there are areas in the northeastern part which are worthy of investigation. The only successful dredging in the Philippine Islands has been carried on in the Paracale district, which is situated in the northern part of the province of Ambos Camarines on the eastern coast of the island of Luzon. It has been described in 'The Mineral Resources of the Philippine Islands', published by the Division of Mines of the Bureau of Science. The placer ground in the vicinity of Paracale generally consists of about four or five metres of barren clay mixed with organic matter overlying a varying amount of gray clay carrying small quantities of gold. Below this is an irregular layer of sand and

quartz pebbles, in places showing large amounts of free gold. Dredging operations have been carried on by the Paracale Gold Dredging Co., a New Zealand corporation; the Stanley-Paracale Co., whose dredge is at present shut down, and the Philippine Gold Dredging Co., which bought a dredge originally erected on the island of Masbate. This latter dredge was found unsuited to the ground on the Paracale river, and was again moved, this time to the Malaguit, where it is said to be successfully working. The Paracale river is really an arm of the sea, with a tide rise and fall of some 5 or 6 ft. The flat in which it runs is perhaps a mile wide near the mouth. It continues about the same width for a mile or more, and then spreads out into smaller flats with ranges of hills between. The total area available for dredging in this flat is estimated at 1300 acres. The average depth is 30 to 40 ft. on the lower river, but higher, where the Stanley dredge is working, the depth is considerably less. The Malaguit river, which flows into the Pacific not far from the Paracale, has been prospected with hand-drills. There is a much larger percentage of gravel and heavy material there than on the Paracale. Several other streams in the same district have been prospected to some extent, with results not altogether favorable, but on the Gumas it is reported that a Bucyrus dredge will be installed in 1911. Low hills and ridges divide the tidewater streams and, except where cleared by the natives for growing hemp, are covered with heavy timber and a dense undergrowth, so that prospecting is difficult. Some engineers familiar with the conditions there consider that there are good opportunities for gold dredging in the Philippines; others, of equal experience, are not so optimistic.

In Burma there are numerous gravel areas, some of which have been worked for generations by the Burmese, who employed a rude method of ground-sluicing. A number of these areas have been more or less thoroughly prospected, and several dredges have been built, a number of which were failures. According to J. Malcolm Maclaren, in 'Gold, Its Geological Occurrence and Geographical Distribution', "of all Burma's numerous auriferous alluvial deposits, none has been considered worthy of extended trial except those owned by the Burma Gold Dredging Co., above Myitkyina. There three dredges were at work in 1907 with results considered so satisfactory that a fourth dredge of greater capacity was being built." Figures for the past year are not at present obtainable, but according to an article in *The Mining Journal*, in November 1909, these three dredges worked 6 days a week for an average of 46 weeks and turned over a total of 1,918,200 cu. yd. for the year, with a total recovery of £32,000, or 8c. per cu. yd. The operating cost, including management, is given as 3½c. per cu. yd. It is possible that dredges will be placed on other properties; a California type, Bucyrus, boat, has in fact been ordered by the Mewaing Gold Co., Ltd. As the success of the Burma Gold Dredging Co. encourages further investigations, doubtless other areas will be found that will prove profitable dredging ground. The Wa country is held to be particularly attractive by some, perhaps on account of being inaccessible to the ordinary prospector. The Was, that is, some of them, are inveterate head-hunters, and while the prospector often figuratively loses his head over a mining proposition, he is not inclined to take too great a chance of doing so literally.

In Japan, according to a report recently issued by the Bureau of Mines,* "from early times many placer workings have been carried on in the river beds or terraces along the river-sides in the districts of Kesen, Wakuya, Hayakawa, Abekawa, Yoshinogawa, etc. Recently they have begun to be worked in many localities in the Hokkaido, and the river Kilung in Formosa. Up to the present time, only the surface placers have received attention, for which reason no gold dredging or underground working has been attempted. The largest nugget ever found in Japan weighed only 27.1 oz. and was found in the gold-bearing gravel at Yesashi. The greater part of these deposits are in the Alluvium, while a few of them are discovered in the Diluvium, yet we never find any Tertiary placers."

Unhealthy climate and difficulties of transportation must be taken into account in many places, and have prevented the exploration of the gravels of certain Colombian fields by modern methods. None the less, several dredges have been installed in different parts of Colombia with varying success. In tropical countries there are many drawbacks that should be thoroughly understood by anyone purposing to invest in mining properties. Often rough mule-trails are the only means of entering a district and the transportation of heavy machinery would be impossible until some kind of a road was built. Attempts to sectionalize dredges have not been as successful as with other classes of mining machinery. In Guiana the only means for transportation of machinery along the rivers is by canoe. One dredge failed to reach its destination because the hull pieces were too large to be taken over the first rapids. They are still to be seen along the trail. The attempt was made to remedy this loss by building a wooden hull on the ground, but in that climate insects and worms destroy wood in a short time. To overcome this trouble, the next hull ordered was made in smaller pieces. Climatic conditions in the tropics are generally trying: the heavy rainstorms during the long wet seasons, and malaria and beri-beri are to contend with. The inefficiency of native labor is also a serious matter, though in some cases it has been possible to instruct natives to operate a dredge, with a white overseer in control. There is always difficulty in securing and maintaining an efficient and honest staff of white labor so far from home, and it is generally found necessary to have a reserve corps to fall back on when occasion requires. All these are things that must be taken into consideration in judging the economic conditions and feasibility of operating in tropical countries. The loss of time from sickness alone is

*'Mining in Japan, Past and Present,' pp. 65. Bureau of Mines, Department of Agriculture and Commerce of Japan, 1909.

not an unimportant item, by any means; one engineer, who has some interesting figures from an extensive examination in Colombia, mentions that his white assistants were incapacitated 16⅔% of the time from sickness. On another trip the young engineer in charge contracted a fever which proved fatal. In foreign countries, as elsewhere, in making investments in dredging, much money may be saved, and disappointment avoided, if prospective investors will insist upon having reports by experienced engineers rather than listening to the advice of optimistic incompetents, and going blindly into enterprises that, to be an economic success, require experience and good judgment in every phase of the work. With the drawbacks of operating in foreign countries, together with unfamiliar government regulations, and other disadvantages incident to operating so far from home, there is little doubt that possible dredging areas in California, and other States, though of lower grade than some that are being at present worked, and of much lower tenor than necessary for profitable operation in foreign countries, will nevertheless be more attractive to conservative investors than the foreign fields. Many investors, however, will be attracted by the higher value of the gravels claimed for these latter places, and some operators, being daring, and far-sighted enough to investigate first and undertake later, if their engineer reports favorably, the risk of new enterprises in a foreign country, will, profiting by their knowledge of the industry, build suitable dredges and make a success of the venture. Investors with little or no experience will, as heretofore, rush in with an insufficient knowledge of conditions and, generally, as might be expected, lose their money. There is no form of mining from which the profits can be more closely estimated at the start than gold dredging, provided experienced judgment has been used in the details of examination and prospecting. Under these conditions and with proper management, it becomes a safe and profitable investment. Gold dredging, or any branch of the mining industry, without honest and efficient management and competent engineering advice, becomes, instead of a profitable investment or a sane speculation, nothing more or less than a wild gamble.

ILLINOIS PETROLEUM PRODUCTION

Figures showing in detail the production in barrels, of petroleum in Illinois in 1909 are given below. They were collected by the U. S. Geological Survey in connection with the Census Bureau.

Geology of the Jarbidge Mining District

By Nelson W. Sweetser

Much has been written during the past year in regard to the wealth stored in the hills of the Jarbidge mining district in Elko county, Nevada, but very little has been told of the hills themselves. The name Jarbidge, called by the Indians 'Ja-Ha-Bich,' is given to the high peaks of the range, and means 'The Devil.' The Jarbidge district is situated between the west and the east forks of the Bruneau river, including the middle fork, or Jarbidge river, a district of about 18 miles in width, and from the Idaho line, which bounds it on the north, southerly for 25 miles, including the head waters of the Marys river. The highest and most prominent range of hills occurs between the Jarbidge river and East Fork, and runs north and south, reaching an altitude of 11,000 ft., yet this range does not determine the drainage of the district, which is generally nearly

north-south, from a high divide running east-west.

Geology.—The district exposes several geological formations, the oldest being the sedimentaries exposed on its western part. These for the most part strike east-west, and dip north at an angle of 60°. They consist of quartzite, limestone, and shales, named in the order of deposition. The beds show a thickness of several thousand feet. No fossils have thus far been found in them.

Granite.—An intrusion of coarsely crystalline gray hornblende granite has faulted and tilted the sedimentaries, and concurrent with or immediately following, the intrusion of the granite dikes of granodiorite have cut the limestones, further faulting them. This disturbed area then underwent extensive mineralization. A long period of erosion followed, which wore down the overlying strata and exposed the granite.

Rhyolite.—Resting unconformably upon this basement complex is a series of Tertiary eruptives, consisting almost entirely of rhyolitic flows. These at

one time covered the larger part, if not all of the district. Erosion has removed them in the western part, except a few remnants upon some of the higher peaks. The greatest thickness exposed in these Tertiary beds is in the Jarbidge peaks, where from the level of the river to the summit of the peaks it presents a thickness of 4700 ft. But even here, 1000 ft. above the river, amid the rhyolites is a ridge of the old basal plane, a stratum of micaceous and graphitic quartzite, striking N.W.-S.E., and exposed for a distance of two miles, being 200 to 400 ft. in width. The rhyolite flows vary in thickness from 50 to 500 ft., and upon the east fork of the Bruneau 12 successive flows can be distinguished where cut through by the river. Their texture grades from the true rhyolites, to the quartz and granite-porphyries, pale green in color. They contain considerable magnetite, which in weathering tints the cliffs with beautiful coloring. The beds rest conformably upon one another in level lines. Between several of them, beds of shale occur which are only a few feet in thickness. Whether or not these are fine-grained eruptives, or of sedimentary origin, could not be determined without petrographic study, but I judge them to be sediments. The rhyolites lie horizontally, showing neither faulting nor folding. The latest eruptives in the district are the basalt flows, which are the lower end of the vast area of the Snake river lava flows. They are crystalline, showing phenocrysts of feldspar. These rest unconformably upon the rhyolite and form a plain, which surrounds the rhyolite upon the north and east sides, rising to a height, near the east fork, of 10,000 ft., and showing several separate flows which are homogeneous.

Erosion.—Across this plain the streams have cut deep canyons, often with vertical walls. As the sources of the streams are approached, which are in the rhyolite area, the canyons widen out, and the sides form steep, grass-covered hills, with even contour, except where sharp needles and cliffs, due to the varying resistance to erosion, stand in bold contrast to the smooth surface. Along the contact between the rhyolite and basalt erosion has been an important factor in the present relief of the district.

Mineralization.—There were two periods of mineralization in the district. The first probably concurrent with, or immediately following the granite intrusion in the western part of the district, where a series of fissures, running N.E.-S.W., cut the limestones and grano-diorites, and a large number of small quartz veins have formed. These veins carry gold and silver, the gold often free at the surface, and some placer has resulted from their erosion. The ores are base, however, at shallow depth, and this fact, coupled with lack of transportation, has retarded the development of the district. The veins in Jarbidge camp occur entirely in the rhyolite. The mineralized district seems to be about three miles long and three miles wide. In the centre of the district are the quartzite strata previously mentioned. Veins occur on each side of its strike, and have several distinctive features. Those on the west, at present the most promising, have the form of a network of veins, whose general strike is N.20°W., with a dip of 80° to the east. These appear to be more of a brecciation of the rhyolite than of clean open fissuring. Evidence is lacking at this time of any movement of the vein-walls, either during the deposition of the mineral or subsequent to it, with the exception of the large Buster vein, which shows slight slickensides upon its walls. There has been no important faulting in the district since the vein formation. The rhyolite forming the wall-rock of the veins is unaltered, and remarkably fresh, only a few inches from the vein matter. The gold does not penetrate the walls of the fissure. The rhyolitic breccia is silicified and distinct walls are often lacking. One would judge the solutions to have been neither very hot nor concentrated, and their chemical activity very slight. The veins upon the east side of the quartzite strike nearly north-south, and dip west at 70°. They are beautifully banded, the bands often being separated with small seams of gouge. The walls are clear and distinct and accompanied by several inches of gouge. The formation of these fissures was accompanied by normal faulting. The veins of the camp vary in width from 6 in. to 12 ft. The values are irregular, and sufficient work has not been done to prove the average value of the ore. The silver occurs both as an alloy with the gold, and probably, as argentite.

Amalgamation Following Fine Grinding

By C. F. Spaulding

Modern metallurgical practice is working more and more toward fine grinding. There is no question but that the finer an ore is ground, up to the point where all the metal becomes free, the better the extraction will be. This is especially true in cyanidation, and the same thing should apply to amalgamation. In my experience of the last few years I have found that the finer the ore is ground the better the extraction. The trouble in fine crushing in stamp-mills is the small capacity per stamp. The high cost in crushing fine is due to this small duty, the labor and power being a constant factor whether two and one-half or five tons be the stamp capacity. The wear and tear on screens, shoes, and dies is higher per ton with finer crushing. Another point in fine crushing in stamp-mills, to 40 mesh or finer, that I have noticed but never seen discussed in print, is the fact that the apdon plates are apt to become covered with a velvety coating of slime, which is about as hard to handle and keep off the plates as the copper salts that bother so many mill-men. If the pitch of the plates be steepened so that this coating does not form, everything goes over them with a rush, the percentage saved by amalgamation dropping sharply. I have evolved the following scheme to get around this. It is open to discussion and the free use of the mill-men.

In this scheme there is to be used no special machinery. Everything is standard machinery, rolls, crushers, tube-mills, which any machinery company can furnish, with the exception of the special amalgamating device, which in case the mill is new can

be built by any machinery company, or in case of a mill already built can be made by any good millwright and installed. Fig. 1 shows a flow-sheet for a 100 to 125-ton unit. Other size mills can be worked up by using one or more units or by increasing or decreasing the sizes of the crushing plant and the tube-mill plant. The flow-sheet is self explanatory.

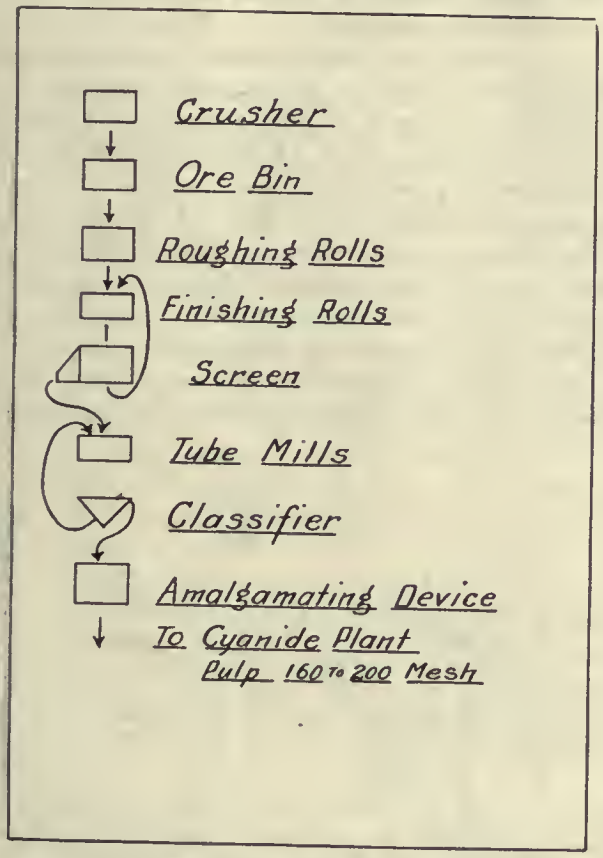

Fig. 1. Flow-Sheet for 100 to 125-Ton Mill.

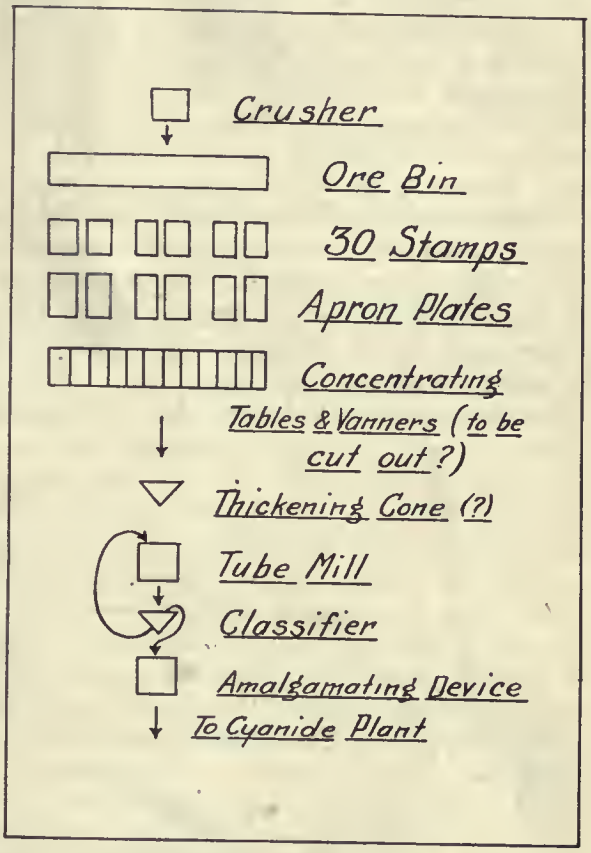

Fig. 3. Flow-Sheet for 30-Ton Mill.

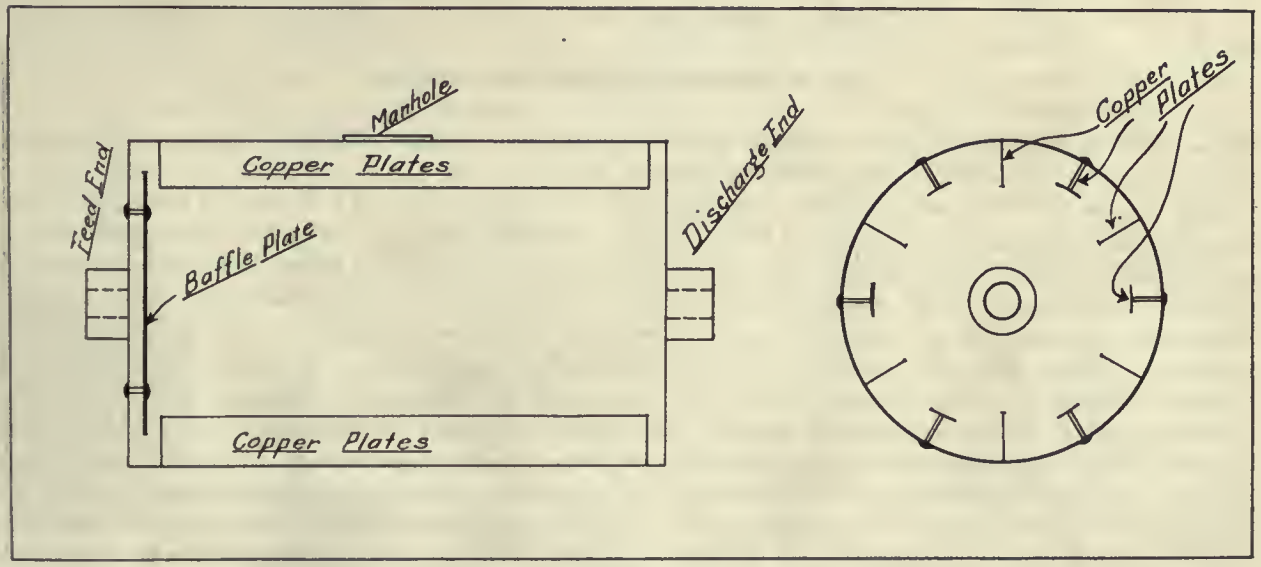

Fig. 2. Amalgamating Device.

Fig. 2 is a rough working sketch of the amalgamating device, to be used in new plants or to be put in an existing mill following the tube-mills, as shown in Fig. 3, which is a flow-sheet for an ordinary 30-stamp mill.

The amalgamating device is simply a revolving tube or barrel made out of wood or iron, revolving on tires or trunnions. Any old cylinder that can be revolved may be used. Have the pulp fed in at one end and discharged at the other, and have copper plates inserted, and if desirable have it lined inside with copper plates. The amalgamating device would ordinarily be 3 to 6 ft. diam., and 4 to 6 ft. long. The length could be increased in proportion to the tonnage. The copper plates should be of such a size as could readily be passed in and out through the manhole, which should be either on one end or the side. The arrangement of the copper plates, the size, and whether it is desirable to line the amalgamating device with a copper plate, cast iron, or leave it bare, is left to the judgment of the designer of each mill. Fig. 2 is merely suggestive. The sketches showing the amalgamating device and flow-

sheets are general in their character and are only intended to give broad plans on which to work. The design of any mill would have to be worked up to conform to existing conditions.

I have had a couple of mills situated so far away from the railroad that it hardly paid to ship the concentrate. Freight charges on the railroad and wagon freight ate up all the profits. At these I built an arrangement on the lines of an arrastre, connected it to the mill shafting, and ground each shift's output of concentrate very fine in cyanide solution. By sliming the concentrate and thoroughly washing it the extraction was brought up to 87 to 93%. Practically the only cost was the consumption of cyanide, as the power used was not great and the mill-men attended to cyaniding the concentrate along with their regular work. The net returns were far ahead of shipping to the smelter, paying freight charges, and smelter charges, and only getting $19 per ounce of gold.

Returning to Fig. 3, by cutting out the apron plates, with the necessary cost of dressing and lost time in hanging up to dress the plates, the concentrating tables and vanners, with the usual cost of attendance and power, and turning the pulp direct from the batteries to the tube-mill, or maybe putting a thickening cone in between the two, would evidently result in great saving in labor, power, and repairs. I believe that in the majority of cases the concentrating table can be cut out. There will be some cases where it may be advisable to retain them. By following the tube-mill with a classifier and returning the spigot product to the tube-mill, the heavier concentrate, which will naturally go to the spigot product, will be re-ground several times and will be much finer than the gangue material. Knowing this and the results obtained in cyaniding concentrates, there is no doubt that in the majority of cases the concentrating part of the mill can be dispensed with.

An ordinary 30-stamp mill with a capacity of 100 to 125 tons per day, costs to erect from $25,000 to $40,000. To re-grind the tailing in tube-mills will call for additional machinery costing close to $5000 erected. A mill on the lines shown in Fig. 1 can easily be erected for $15,000. The building is much smaller and the cost of machinery, freight, and labor to install, is also much less than for a 30-stamp mill. The operating cost, labor, repairs, lost time, heating, etc., will be much less than in the average 30-stamp mill. One man on a shift, outside of the crusher and power men, who will be the same in both cases, will handle this mill, as against two or three men on a shift in the stamp-mill.

By grinding in cyanide solution in the tube-mill, the cyanide plant can be simplified somewhat. In ordinary stamp-mill practice the pulp is in contact with the copper plates 12 to 15 seconds. In the amalgamating barrel the pulp can be in contact nearly as many minutes. Thus a larger percentage of extraction may be expected. By grinding in cyanide solution either dilute or standard strength, the gold will be cleaned and in better shape to amalgamate than in ordinary stamp-mill practice. It is true that the copper plates will have a tendency to harden and the amalgam crumble, but the amalgam cannot get away. It will be caught in the cyanide plant.

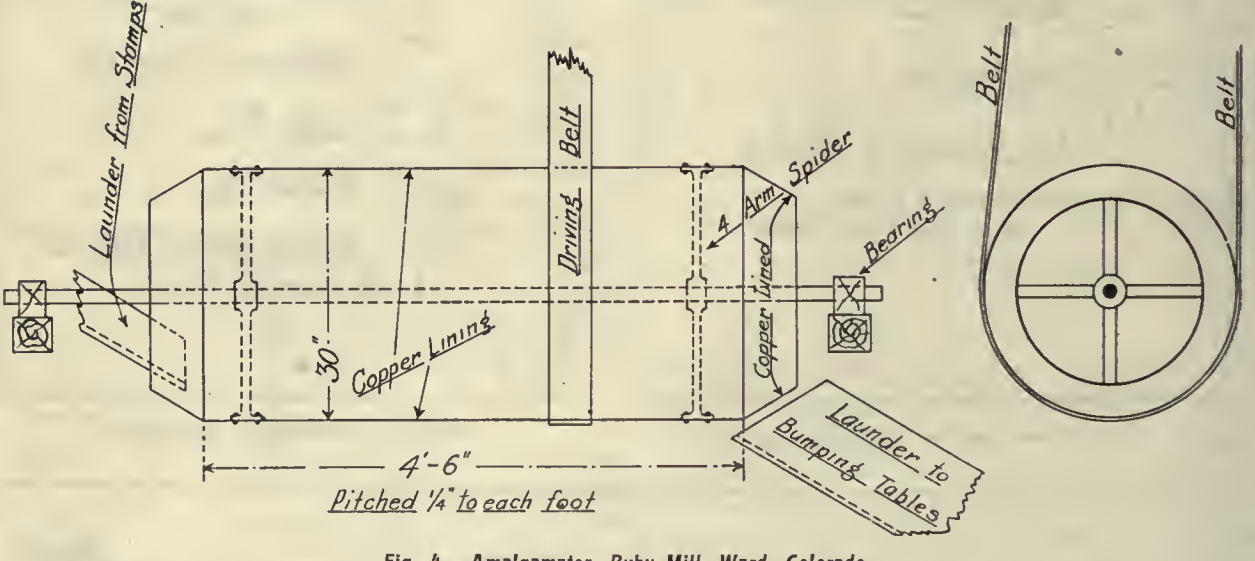

Fig. 4. Amalgamator, Ruby Mill, Ward, Colorado.

It will work out in a number of cases that because of the fine grinding the extraction by amalgamation will be so large that there will not be enough gold left in the tailing to warrant the cost of cyaniding. The most general occurrence of gold is either free gold, or gold enclosed in pyrite. In the case of the pyrite the gold is generally conceded to be mechanically intermixed rather than in chemical combination. That being the case, if the particles of pyrite be ground fine enough the gold should be liberated, and amalgamation alone will be sufficient. In an existing stamp-mill the fine-mesh screens can be cut out, but with 6 or 8-mesh screens the pulp should be sent to the tube-mill, and thus the duty of the stamps will be increased 15 to 25% or more: all at a less cost per ton. In the old Ruby mill a few miles west of Ward, Colorado, is a rotating amalgamating device. See Fig. 4. This mill has been shut down for a number of years, but I understand the amalgamator worked very satisfactorily. The ore was ground by steam stamps, passed through the amalgamator, and over Gilpin County bumping tables.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Laboratory Work in Secondary Schools

The Editor:

Sir—I am engaged part of the day in imparting elementary laboratory instruction in chemistry and physics to the boys and girls of one of our secondary schools. I have full liberty in my choice of what shall constitute the curriculum, the end aimed at being a maximum amount of (a) mental training, (b) manual training, and (c) practicability with a minimum amount of (d) waste. Inasmuch as the course includes assaying and kindred subjects, it occurs to me that a large number of your readers being practical men, should be in a position to give valuable advice on this subject. With a view to starting a discussion, I am appending a set of questions, which I hope will elicit some information from your readers.

1. Does laboratory work in combination with textbook lessons afford the same amount of mental training as the more academic branches of elementary instruction? If there develops a different line of mental training, what are the advantages and disadvantages of laboratory work from a practical standpoint?

2. Does laboratory work afford the same degree of manual training as instruction in a wood-working or metal-working trade, that is, carpentering, cabinet-making, blacksmithing, or tinning? What would be the value of laboratory work taken in conjunction with one of these trades?

3. Is instruction in assaying much improved by preliminary courses in elementary chemistry and analysis? What other courses would be advantageous in conjunction with assaying in an elementary school?

4. Is a knowledge of elementary chemistry and physics of any great practical value to the average pupil, that is, to the boy (or girl) not expecting to pursue the studies any further or to engage in any pursuit depending primarily upon chemistry and physics? For that matter, is the proportion of occupations or trades in which a knowledge of elementary chemistry and physics is of some value, great enough to warrant the average boy (or girl) pursuing such a course at school? Is this proportion increasing or decreasing?

5. Does the education which a boy may receive in a laboratory tend to wean him from the manual work which he may be called upon to perform? For example, to the boys behind the plow, is the increased interest in their work, due to a knowledge of the relations of plant growth to the chemical ingredients of the soil, more than offset by the additional tediousness of manual labor to "those who have been educated away from it"?

6. Is laboratory work apt to be of practical value to our girls? Would the number of short-weight scales and measures recently confiscated in New York city, have been diminished, were our housewives more generally trained in laboratory work?

7. Is the amount of 'waste', that is, work and instruction of an unpractical nature, any greater in the laboratory than in the academic branches of instruction?

8. How much of a pupil's time can be most profitably devoted to laboratory work?

PEDAGOGUE.

San Francisco, California, December 16.

Superficial Indications of Ore-Shoots in Depth.

The Editor:

Sir—The recent contributions by Messrs. Storms, Janin, and Gordon in the *Mining and Scientific Press* of October 22, November 19, and November 26, respectively, and entitled 'Superficial Indications of Ore-Shoots in Depth', are interesting and a step in the right direction. I do not know of anything that could be more helpful to the prospector than a discussion of this kind by men of wide experience, and who naturally are more keen observers than the average miner, especially the one whose whole interest is centred on his day's pay and what a glorious time he is going to have after he receives it. Mr. Storms' contention that "gulches, or natural depressions crossing the strike of the lode or vein, are the physical expressions of disturbances beneath the surface, and it is rarely, if ever, that an ore-shoot will be found to extend from solid unbroken ground beyond such surface evidence of disturbance", I have found here in Arizona, and elsewhere, to be warranted. Especially have I noticed this phenomenon where a vein leaves an anticline and enters a syncline; it either becomes barren, or nearly so, or feathers out. It seems natural that where a lode traverses unbroken ground and continues uninterrupted for a long distance, that there should be hope of continuity in depth. Quoting from Mr. Lindgren: "In considering the probable permanency of a given vein, its general character must be taken into consideration. Continuous, well defined outcrops and wide bodies of quartz are in general good indications of the maintenance in depth, as is also any evidence of strong faulting and movement. A fissure which can be definitely proved to extend only a short distance will, in all probability, be found to be correspondingly limited in depth". But as there are exceptions to all rules, so there may be in this, but up to date they are scarce and far between. Another matter I would like to draw attention to is the alteration of the country-rock along veins. This may not be a direct indication of continuity in depth, since most superficial alteration is due to weathering, yet that by chemical action is not, and can only have taken place at great depth, and under great heat and pressure. It is therefore not unreasonable to believe, where such alteration characterizes the wall-rocks of a mineral vein, that its presence is a good indication of continuity in depth.

I am only a miner and prospector, and not a mining engineer or geologist, but could not refrain from expressing my pleasure and appreciation of the matter so ably advanced by the writers mentioned above, and I am sure that such a discussion and its continuance can only be of benefit to those who read it.

Quartzite, Arizona, December 15.

Avino Mines Company

The Editor:

Sir—I have been interested in the remarks contained in the letter of your London correspondent, printed in the issue of October 8, touching the Avino Mines of Mexico, and the subsequent discussion by Mr. Nichols and Mr. Channing, because I at one time, ten years past, made an examination of the Avino mill. I believe I will not be violating professional ethics in supplying a bit of the data which I have, and I may be able to throw some light on this interesting problem.

The following analysis, furnished by the chemist, was of the ore treated in March 1901:

	Per cent.
Insoluble	71.6
Alumina soluble in acid (Al_2O_3)	2.9
Lime (CaO)	0.3
Iron (Fe)	7.3
Zinc (Zn)	1.8
Lead (Pb)	5.2
Copper (Cu)	1.65
Sulphur (S)	5.6
	96.35

From this and other analyses and careful examination of the ore, I considered the mineral composition to be as below, essentially quartz with silicates, and probably some hydrous silicates, of the bases.

	Per cent.
Silica	66.7
Ferrous oxide	4.6
Soluble alumina	2.9
Insoluble alumina	4.8
Lime	0.3
Pyrite and marcasite	5.75
Galena	4.20
Chalcopyrite	3.33
Zincblende	1.89
Cuprite and malaconite	0.83
Malachite and azurite	0.18
Chalcocite, bornite, etc	0.23
Cerussite	0.95
Anglesite and other lead minerals	1.00
Smithsonite and other zinc minerals	1.00
Argentite	0.06
	98.12

The remaining 1.88% consists probably of alkalies with possibly some combined water, resulting from the decomposition of the porphyry, together with traces of manganese and magnesia. At that time the mill included jigs treating three sizes of material, followed by Wilfley tables and an experimental canvas plant. The 'coarse jigs' treated material between 5 and 3¼ mm., the 'medium jigs' from 3¼ to 2 mm., and the 'fine jigs' from 2 to 1 mm., the tailing from all of these machines going to waste. The clean galena carried 1.7 kg. silver per ton, and the clean chalcopyrite about the same. Zincblende as pure as could be picked carried 2.7 kg. silver per ton. The pyrite furnished an interesting example of precious metal occurrence, in that the portion which was saved on the coarse jigs carried only 0.15 kg., while that saved on the Wilfley table contained 2 kg. of silver per ton. From the above analysis it will be seen that the Avino ore was, in 1901, quite complex, and its treatment no simple problem. Brief investigation showed the gross saving on the coarse jigs did not pay the cost of power and water necessary for their operation. An examination of the tailing pile showed at once losses from three principal sources: (1) included grains in tailing from both jigs and Wilfleys; (2) fine grains in the finer tailing; (3) slime. The first loss was by far the most important, the included grains being found in tailing as fine as 40 mesh. This was doubtless a result of the change from the original design of the mill which had included re-grinding with Chilean mills, but the machines purchased, of local design, had been thrown out. My investigation satisfied me that on ore of the character coming to the mill at that date, given proper crushing followed by the necessary re-grinding and with efficient machinery for treating the fine, the recovery could be approximately doubled. I believe nothing was done toward making the needed changes, although I am not familiar with the history of the property. I have been told that several years later Mr. Nichols reached conclusions similar to my own, and in the last annual report of the present manager, R. H. Jeffrey, I read with interest this paragraph concerning Mr. Woods' tests: "It was clear from the earlier tests, the results of which have been reported, that finer grinding was necessary to liberate the metallic particles carrying values from the matrix; a 40-mesh screen was therefore adopted."

Geo. A. Packard.

Butte, Montana, December 15.

Climatic conditions undoubtedly change in long periods of time. In California during the later Tertiary age the climate was wholly unlike that of today. There are few large rivers in California, and these are in the broad level valleys. All mountain streams are found in deep narrow ravines, with heavy grades. In the period during which the ancient, now 'dead,' rivers formed, the streams carried vast amounts of gravel, and even boulders were moved along by the currents of those great streams. The channel of the Hidden Treasure mine, on the Forest Hill divide in Placer county, is 1600 ft. wide, and some of the channels near Dutch Flat and Gold Run were even larger than this. In the Happy Valley channel, near Mokelumne hill, in Calaveras county, large boulders were found with comparatively fine gravel, several feet above bedrock, showing that the streams of those days had both great volume and heavy grade.

Missed holes are the ever present danger of the miner, and often difficult to detect. A miner seldom runs into more than one during his lifetime.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The free atmosphere weighs at the rate of 1 lb. for each 12 cu. ft. at sea-level at 32° Fahrenheit.

A magnetized iron rod is useful in removing from the drill-hole pieces of drill steel broken from the drill-bits.

In hydraulics 550 foot-pounds per seeond is taken as the equivalent of one horse-power (33,000 foot-pounds per minute).

Glaucophane is a blue variety of hornblende. Though abundant in the Coast Range of California, it is not so elsewhere in the West.

Native antimony is not unknown; it occurs in at least two localities in California, one in Riverside county, near Corona, the other in Kern county in San Emedio canyon.

Never close valves in a water-line hastily, as the sudden arrest of the moving column of water produces what is termed water hammer, which if very severe may burst the pipe.

Gold occurs in beach sands at several places along the California coast, but none of these deposits has ever proved profitable, though many and expensive attempts have been made to work them.

Iron sulphide concentrates can be reduced to matte in the reverberatory furnace, only the addition of a small amount of copper in the form of high-grade ore being necessary to act as a carrier of the gold.

If the amalgam does not retort up to expectations, the natural conclusion is that the expectations were not justified by facts. The disappointment may be due to any of several causes, most often to failure to properly clean the amalgam before retorting.

Quartz-mill tailing makes good mortar if not too fine, and if it is practically free from sulphide. If the latter be present it will decompose and the acid will attack the lime, forming an efflorescence of calcium sulphate, and it may disintegrate the mortar.

One per cent metallic tin in an ore is 20 lb. per ton of ore, and at present prices is equal to about $8 per ton. There are few veins of good size that carry more than $8 per ton in gross value. Neither the mining nor the metallurgy of tin is difficult, but the discovery of a profitable mine is.

Pyrite is nowhere utilized as fuel except in what is termed 'pyrite' or 'pyritic' smelting. In this process the sulphur of the pyrite supplies a portion of the fuel, only a relatively small amount of carbonaceous fuel, coke, being added, usually about 7 to 10 per cent.

That an orebody go down to great depth is not nearly so important as that the ore be of profitable grade, even if it occur entirely as a superficial deposit. Such orebodies have the advantage, at least, of offering no incentive to expend large sums in the search for more ore in depth when the deposit is exhausted.

The usual measurement of quartzose orebodies is 13 cu. ft. per ton, but this varies with the percentage of sulphides present, and their kind. Heavily sulphuretted ore requires considerably less than 13 cu. ft. per ton. Homestake, South Dakota, unoxidized ore, containing about 10% finely disseminated pyrite and pyrrhotite, requires but 10 cu. ft. per ton.

Rapid drilling by hand is not accomplished by use of heavy hammers and forceful blows, but by hammers of proper size handled by men who know how to strike the blow that will cause the drill to cut and keep the bottom of the hole clear so that the drill is working on solid rock and not on a lot of loose fragments. This is an art and is only learned by experience.

Polaris, the North Star, is probably the star most familiar to all surveyors and to most other persons. It is interesting, therefore, to know that Polaris is really three stars, though appearing as one, even through ordinary teleseopes, but by means of the great Lick teleseope on Mount Hamilton, California, it was learned some time since that it is comprised of three distinct stars which revolve about each other.

Concentrate produced in quartz-mills often contains a noticeable amount of sand and slaty material, which is of lower density than the sulphides with which it is mingled. When this occurs there is something radically wrong in the work; either the concentrating machine is not adjusted properly, it is over or under loaded, or the operator does not fully understand his business. Another, and perhaps the most common cause of dirty concentrate, is the attempt to make a separation of sulphides from gangue without sizing. Good work cannot be done if the pulp be not first sized. Some millmen overcome this obstacle in a measure by running the concentrate from several machines over one, recleaning it, but this is a makeshift which sizing and classification will obviate.

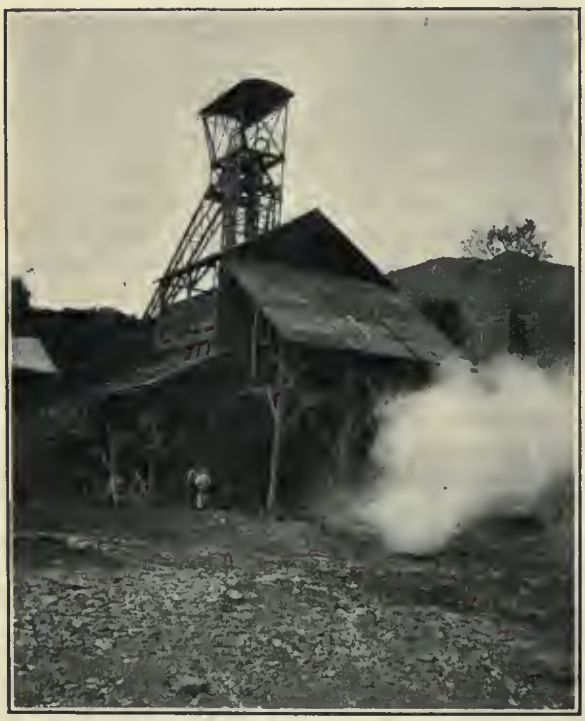
In the lead blast-furnace, when copper occurs in the lead ore, the object is to cause the copper to pass into the matte, which it does as cuprous sulphide, so long as there is sufficient sulphur present to form this copper matte. Where copper, iron, and lead, are all present in the charge, the copper must first be satisfied in its affinity for sulphur, the iron and lead taking up what remains. If there is not enough sulphur present to take up all the copper as matte, the copper will form an alloy with the lead, sink to the bottom of the well, and will there, in all probability, close up the passage of the lead-well. The flux will vary with the silica, lime, iron, and other minerals in the ore. The relation of sulphur to copper is the principal thing in these charges of mixed ores.

Special Correspondence

MEXICO

Competition Among Custom Smelters.—Operations in Hostotipaquillo District.—Electric Power.—Interest in Taxco District, Guerrero.

The custom smelting concerns of Mexico are competing for the ores of the Republic, and as a consequence operators are securing more favorable terms than formerly. The agreement to respect one another's territory, which for a long period was lived up to in a way unsatisfactory to mine owners, has been abandoned. Siliclous ore that will stand shipment is scarce, and some contracts for such ore are being made at prices that allow little margin for smelting. This active competition probably will continue until there comes a material increase in the production of shipping ore. The Aguascalientes plant of the A. S. & R. Co., the largest of the 'trust' smelters in Mexico, is now treating only about 15,000 tons per month, or one-half its tonnage capacity.——The Hostotipaquillo and Etzatlan power lines of the Chapala Hydro-Electric Co., of Guadalajara, will be



Amparo Mine Near Etzatlan.

established in January. In the former district power will be immediately received by the El Favor Mining Co., and in the latter by the Amparo Mining Co. At El Favor a 20-stamp concentrating and cyaniding plant was completed late last year, and has since been awaiting the transmission of power. Recently two additional tube-mills and other equipment were installed, and when the mill begins operating it will treat about 125 tons of ore per day. A big tonnage has been proved in the El Favor mine, and stoping will be commenced as soon as the mill is started. The current will be transmitted from the transformer station of the El Favor company to the Casados, Mololoa, and Mirador mines, the Amajac custom reduction works, and the Marquetas plant of the Virginia & Mexico company. The Mirador Mining Co., controlled, as is El Favor, by the Makeever interests of New York, will install reduction machinery adjoining that of El Favor, using the same building. For this purpose 15 stamps, concentrating, and cyaniding equipment have been ordered. Time will be saved by this arrangement, and there will be economy in operation. The Mirador properties are but a short distance from the El Favor mill.——The Virginia & Mexico company, which built the first reduction plant in the Hostotipaquillo, has suspended operations, the high percentage of manganese in the ore having prevented a satisfactory extraction by concentration and cyanidation. A tentative arrangement was made whereby the Virginia & Mexico plant could be used by the Espada Mines Co., operating near Marquetas, but the arrangement has not yet been approved by the former company.——The Mololoa mine, a widely known antigua of the district, has been taken over from the Mololoa Mining Co., a Toronto organization, by W. M. Mathews, of Hostotipaquillo. A body of high-grade ore has been opened, and shipments are being made.——The Magistral-Ameca Copper Co., of Los Angeles, has shut down its concentrator in the Ameca district of Jalisco, so the plant can be enlarged to give it 150 tons capacity. French interests recently purchased a large block of stock in this company.——The Porvenir tunnel of the Tajo Mining Co., San Sebastian district of Jalisco, on which work has been in progress for three years, has cut the old Tajo vein at depth, in which ore assaying from 2 to 6 kg. silver per ton was found.

There is promise of much benefit to the old Taxco district of Guerrero in the plans of Chicago men to give it rail connection with the Balsas line of the National Railways at Naranjo. The Taxco-Naranjo-Guerrero railroad has been incorporated under the laws of Arizona to operate under a State concession granted to F. E. Olendorf, a mining man of the Taxco district, and it is expected to have the line in operation before the end of 1911. It will be a narrow-gauge road, and about 30 kilometres in length. The grades near Taxco and Naranjo will be heavy. The road will greatly facilitate the shipment of machinery, supplies, and mine and mill products. The Taxco Mines of Mexico, Ltd., the British syndicate now in control of the old Rosario properties, and which started development last June, is now developing ore reserves. The present reduction plant is to be remodeled and enlarged. The Espiritu Santo Mining Co., of Mexico City, owning some of the famous antigua properties of the Taxco district, is regularly shipping high-grade ore, and has a big tonnage of milling ore in the mine. A cyanide plant of 150 to 200 tons capacity will be built. Plants for concentration and cyanidation of 100 tons of ore per day are projected by the Cedral-Lajuela Mining Co., of Boston, and the Mora y Milagro Co., of Mexico City. The Suitepec Light & Power Co., now transmitting current to the Zacualpan district of the State of Mexico, has plans for extending its line to the Taxco district. The supplying of power to Taxco mines and mills also enters into the plans of a company recently formed to generate power on the Balsas river.

MELBOURNE, AUSTRALIA

Bullfinch Boom. — State Coal Mine. — Profits of Mt. Lyell. — Labor Problem at Broken Hill.

The great event recently was the discovery of ore at the Bullfinch claim near Southern Cross, the Yilgarn district, Western Australia. This has attracted much attention, and a syndicate of stock exchange dealers in Adelaide has obtained leases adjoining the Bullfinch. W. J. Loring, of Bewick, Moreing & Co., and Richard Hamilton of the Great Boulder have testified to the richness of the ore on the Bullfinch lease, and a boom has resulted. Newspapers that should have known better lent themselves to the flutter, and so a frantic rush of speculators into the Adelaide market took place. In Melbourne, *The Argus* kept its hand on the safety-valve, and checked most of the attempts, only half a dozen flotations being carried through. When it is understood that many of the companies were floated to deal with ground into which not a pick had been put, and when the length of the shoot of gold was undetermined, the stupidity of the boom can be measured. The largest company promoted in Melbourne had an issue of 200,000 shares, of which the promoters took 60,000 for £7500 cash, for a block of leases, the main merit of which was that they had been pegged out by Doolette and Shallcross of the Bullfinch mine. It will be luck indeed if the outcrops should prove to carry profitable ore. The State Government of Western Australia

has been inclined to philander over the boom, having given but a half-hearted warning to the public that things have gone too far. As the State Geologist, A. Gibb Maitland, has been inspecting the locality, something better may be expected. Unfortunately, Government officials too often are not the frank critics they should be. It will be refreshing if Mr. Maitland is found to be an exception.—— The more the facts in respect to the State coal mine of Victoria are disclosed, the more the old story of the folly of having State management of business affairs is demonstrated. In the first place, because a strike existed at Newcastle, an impractical Minister of Mines was induced to sanction a rush expenditure at the Powiett to furnish coal for the railway service. By the time the strike was over, about 4000 tons had passed into the hands of the department. The result was that £21,000 was lost up to June 30 last, as against a total expenditure of £36,000 on capital account, and £46,600 on working account. Had the position and future mining work been accurately estimated in the first instance, this loss would have been averted, because the rush expenditure would have been seen to be unwarranted. As it is, the coal is now being pushed into the market against private producers, with the result that some of the mines are having to close down. The Newcastle Coal Vend in New South Wales is watching the development of this State coal mine with mingled feelings. Victorian consumers have been large buyers, and if they are to abandon Newcastle coal the position of affairs there will become serious. As it is, there is a big shrinkage of trade owing to the loss of contracts in the East. The State labor party of New South Wales wants to nationalize the mines there, but if they propose to buy the owners out, then the country will have to provide a vast sum. If the party decides to follow the policy of Victoria, then the private mines will have to shut down. Some of the labor party are staunch advocates of such a policy. If the shipping combine, the members of which are large coal owners, could be hit in that way, no one would feel regret, as it pinches the public in the matter of freights and fares, and in the price charged for coal.——For the first time in several years the Mount Lyell Mining & Railway Co. of Tasmania, the greatest Australian copper producer, has had to knock off the bonus it has been paying to its shareholders over and above the usual dividend. The reason given is the low price of copper, which averaged about £55 10s. for G. M. B. The profits were down to £90,000 for the past six months as against £115,000 for the previous term when the average price of copper was over £59. While financial results have been disappointing, from a mining standpoint the property is in a better position than it has ever been. This is strong testimony to the splendid metallurgical skill and enterprise of two American mining engineers, Robert Sticht and A. L. Dean. The Mount Lyell orebody consists of a huge pyritic mass, and the company is fortunate in having also the North Mount Lyell, a highly siilcious deposit averaging 6% copper, whereas the Mount Lyell ore is under 0.7%. At one time it looked as if the North Mount Lyell deposit was likely to give out, but at the 850-ft. level the ore-shoots enlarged beyond expectations, and several of them have been proved down to the 1100-ft. level. Therefore, the mine reserves now amount to 1,000,000 tons. This estimate is on a conservative basis, and a reasonable conclusion is that there is 18 months' work in sight down to 1100 ft. This level has been only partly opened, and the interesting feature is that the grade of the ore still remains at the average of 6%. The Mount Lyell ore serves simply as a flux for the North Lyell ore, and some of the pyritic ore is used for the manufacture of superphosphate, a business in which the company is engaged on a large scale in Victoria, South Australia, and Western Australia. A portion of its profits and some of its reserves have been absorbed in putting up superphosphate works in the different States, but as that expenditure is now at an end, the money will be used to build up the reserves again and probably to return to the old scale of dividend.——At Broken Hill the labor question is beginning to cause anxiety. The Proprietary mine is still shut down, thus keeping 1800 men out of employment, as the directors refuse to mine at the loss that would be involved in paying the scale of wages fixed by the Federal Court of Arbitration. The aim of the unions at Broken Hill is to compel all workers to become members of their associations. They want to do this before the end of the year, so that when the present award of the court expires they will be able to present a solid front to the companies. It is thought that the companies may agree to pay 9s. per day to unskilled labor, but it is not likely that they will consent to increase the wage of the miners, and they certainly will not abandon their old position of antagonism to the union demand that they must give preference to unionists. Generally speaking, the wages at Broken Hill are the highest earned in Australia when the cost of living is taken into account. At present labor is exceedingly scarce there.

DENVER, COLORADO

Committee on Legislation.—Franklin Guiterman's Speech.—Cripple Creek Operations.

The coal mine disasters during the past few months have directed public attention to that industry. Governor Shafroth has appointed a committee to investigate the conditions in the several coal mining districts of the State, and to recommend needed legislation. The report of this committee is expected in the early part of January so that action may be taken at this session of the legislature. It will be interesting to note the recommendations of this committee, made up as it is of three very able men who are not in particularly close touch with coal mining. The problem is one of too great importance to be acted upon hastily, and it is suggested that these recommendations should be mailed to every coal mine operator and mining engineer in the State, asking for his views upon the same and for any additional suggestions which he might care to make. This would take considerable time, but when the answers were all in and summarized, there would be at hand a mass of information from which a very sensible statute might be drawn. The work which the Denver branch of the American Mining Congress is doing in shaping legislation needs special mention at this time. If this organization will only broaden the scope of its activities to include coal mining and its legislative needs, as well as metal mining, it will render a great service to the State. ——No public utterance, in recent years, on Colorado mining, has caused as much discussion as the speech of Franklin Guiterman, local manager of the American Smelting & Refining Co., before the American Mining Congress in Denver. Mr. Guiterman told some very plain truths about the decline in mining in this State for the past ten years. Correspondents for the local papers have been busy since that speech offering suggestions as to the cause of this decline. The A. S. & R. Co. has naturally come in for a great deal of criticism, and some praise. In discussing reasons for the many idle smelting plants throughout the State, few writers have been willing to concede that their building may have been ill-advised in the beginning or poorly managed in the end. The Forest Service has also received its share of abuse. To one not familiar with the actual conditions, it would appear that a prospector could not enter a National Forest in Colorado. This is absurd and hurts mining. There is no place where prospecting can be done to better advantage than on a National Forest when a man really means business. One of the strongest deterrents to prospecting in Colorado is the fact that so many of the good prospects have been patented and now lie idle. There is not the same incentive that there once was. Should the land laws of the country be so changed that it would be necessary for a claim holder to develop his property in a consistent, intelligent manner, within a given time, then there would be some activity. This holding a claim simply to get the unearned increment from some other fellow's work is one of the reasons for the present predicament.—— The contract on the Cripple Creek drainage tunnel has been completed, and the El Paso company is now driving the

tunnel ahead on company account. No clearly defined water-course has been cut as yet, although the tunnel is in very wet ground and makes about 2500 gal. per minute in excess of what comes from the El Paso drill-hole. The November production from the district showed a larger tonnage with a lower average value than usual. The gross bullion value was $1,376,697. Many of the mining companies which intend to resume operations on company account are considering the establishment of a change-room system. It is the surest way of dealing with the high-graders. Honest miners will not object to having their personal comfort provided for, and if others are so particular that they cannot abide shower baths, lockers, and dry clothes they are surely too finical to work underground.

BULAWAYO, SOUTHERN RHODESIA

Historic Celebration in Rhodesia.—Growth the Result of Mining.—Record of Globe & Phoenix.—British South Africa Company.

At the commencement of this month (November 1910) Rhodisia celebrated her 'coming of age.' Twenty-one years ago a hardy band of pioneers took possession of Mashonaland, a country which was then an absolute terra incognita, a land which only a few daring hunters, traders, and explorers, and a few enthusiastic missionaries had visited. Later came the Matabele war, the flight of Lo Bengula, the

Map of the African Goldfields.

savage king, and the occupation of the land of the Matabele. Twenty-one years ago the wild 'veld' clung around Mount Hampden. Today Salisbury stands there, the capital of a prosperous country, a town with miles of streets, imposing law courts and administrative offices, a dozen and a half good hotels, a theatre, etc. Bulawayo, built almost on the site of Lo Bengula's old slaughter kraals, is the proud capital of Matabeleland. It has grown more rapidly even than Salisbury, and as I write these lines I may take my eyes off my pen for a moment and see great broad streets decked and festooned with bunting, for the King of England's uncle will visit Bulawayo next week.

Nothing has contributed so much to the development of the country as mining. Up to date Rhodesia has produced gold, coal, silver, chrome iron ore, lead, diamonds, and other precious stones, wolframite and scheelite, copper, asbestos, and antimony of a total value of over seventeen and a half million pound sterling. And it is perhaps fitting that at a time when the country is celebrating her coming-of-age anniversary, the premier mine of Rhodesia—the Globe & Phoenix—should get up a record return of £65,000 as the result of one month's production. Never before has any single Rhodesian company produced such a large amount of gold in one month, and the achievement of the Globe & Phoenix mine not only eclipses all other Rhodesian outputs for individual mines by at least £15,000, but establishes the fact once and forever that Rhodesia is not merely a country of small rich quartz shoots of no enduring character, but that it contains at least one large mine as well as a number of small ones.

As a matter of fact Rhodesia contains many large properties, mines which may be relied on to operate equipments of 50 or 60 stamps for several years to come—mines like the Shamva, the Falcon, the Gold Schists, and the Giant. There are, too, numerous properties which are as yet in their veriest infancy, but where orebodies at least 35 ft. in width are being exploited. I know of two or three such occurrences which assay from 4½ to 5½ dwt. right over this width and which are admirably situated with regard to cheap working facilities. As the country opens up, the cost of mining, reducing, and treating ores in Rhodesia will of course diminish greatly, and I predict that in the very near future a great deal will be heard of those low-grade Rhodesian deposits.

Although the Chilean mill has found but little favor in the Transvaal a number of these reducing machines are employed in Rhodesia. Some of the most important mines in the country are employing them and are reported to be obtaining very satisfactory results from their use. Hitherto all the Chileans at work in the country have been run on the high-speed principle, and it is therefore interesting to learn that endeavors are now being made to introduce slow-speed Chilean mills in Rhodesia. It is contended—and with reason—that to many of the smaller mines of Rhodesia situated at a considerable distance from the railway a minimum repairs and renewals bill is an absolute essential, since in many instances the difference between a high and low renewals account may well represent the difference between profit and loss to the workers of the mine in question. The results that will accrue from the operation of slow-speed Chileans in which large capacity is obtained by grinding the ore under great pressure instead of at high speed and little pressure are certain to be followed throughout the country with great interest.

While practically every important South African mining house secured interests in Southern Rhodesia last year or early in the current year, it has been noticeable that until quite recently the great firm of H. Eckstein & Co., in whom the South African interests of Wernher, Beit & Co. are vested, had rather held aloof from acquiring any properties in either Matabeleland or Mashonaland. Wernher, Beit & Co. have, of course, a large stake in the country represented in the firm's participation in the British South Africa Co., and the Eckstein's have for some time past had a local representative with headquarters in Salisbury, Mashonaland. But it is only within the past month or two that the company has actually acquired separate and individual interests in Rhodesia, and it is of course a 'bull point' for the country that at last the Ecksteins have invested considerable sums of money in acquiring blocks of claims and options in both Matabeleland and Mashonaland. A few days ago interests in the Mazoe district to the north of Salisbury were acquired, and I am now given to understand that the firm has under consideration the taking up of certain properties in the Gwanda district to the south of Bulawayo. Around Gwanda numerous important discoveries have been made in schist and scorodite within the past few months, and in addition to the Ecksteins other important South Africa mining houses have representatives busily engaged in the inspection of properties in this portion of Matabeleland.

Very good results are attending the development of the Antelope Gold mine situated about 60 miles to the south of Bulawayo. The company is controlled by the Rhodesia Exploration & Development Co., and Abe Bailey is one of the largest shareholders in the property. A sound scheme

of development is being carried out at the mine, which when crushing commences should be in possession of a substantially larger tonnage of ore in sight than have most Rhodesian mines when milling operations have begun. So satisfactory have been the explorations in drifts and winzes during the past two or three months that plans for equipping the mine with reduction and treatment plant are now receiving consideration. The stamps will weigh 2000 lb. apiece and will be the heaviest gravitation heads at work in Rhodesia. They will be supplemented by tube-mills, but I am unable at present to state what the capacity of the plant will be.

TORONTO, CANADA

First Selling of Porcupine Stocks.—Dividends of Cobalt Companies.—Nipissing Output.—Codification of Mining Laws.

The first important offering of Porcupine mining stock to the public was made this week, when shares of the Hollinger Gold Mines, Ltd., which had been underwritten at $3.50, were placed on the market and sold rapidly at prices ranging from $4 to $4.70. The Hollinger, which is capitalized at $3,000,000, with shares of the par value of $5, was organized by the Timmins-McMartin syndicate, and owns four claims. A three-stamp mill has been in operation on the property for some time, and it is claimed that enough gold has been produced to pay the cost of development to date. Orders received from a distance indicate that the flotation has excited widespread interest. Several of the leading Cobalt companies have recently paid big dividends which have tended to keep up prices of these particular stocks, but the general list has been weak, non-dividend issues steadily declining. La Rose has announced its regular quarterly dividend of 2% only, to the disappointment of those who were figuring on the restoration of the old rate. The directors announce their adherence to the policy of creating a large cash reserve before increasing dividends. The Nipissing pays the usual quarterly 5%, with a 2½% bonus. The Buffalo has declared three dividends, amounting to 13%. Crown Reserve, in addition to its quarterly 6% dividend, gives a 9% bonus. Trethewey has declared a division of profits equal to 10%. The Temiskaming has declared a 3% quarterly dividend and a 5% bonus. The Right of Way pays its customary quarterly 2%. This is a favorable showing, and, taken in connection with the market prices of the stocks, would seem to indicate an upward movement. The shareholders of the Trethewey are to be asked to sanction an increase of the capitalization from $1,000,000 to $2,000,000 by the issue of treasury stock to be used for the acquisition of other properties.——The Peterson Lake and Nova Scotia companies, which have been contending over a strip of valuable territory, have arrived at an agreement under which the disputed area will be worked and the proceeds retained by Peterson Lake until the courts decide how it shall be apportioned.——A. M. Thomsen, of California, who has a conditional lease of the Green-Meehan property, is having it unwatered preparatory to a thorough inspection. He is of the opinion that the mine may have been badly worked and the orebody overlooked.——Some good finds have been made at the Beaver, where development has been in progress during the last quarter. In cross-cutting from the main shaft on the 300-ft. level the big vein was cut at that depth, yielding good silver ore. About 275 ft. north of this point a 7-in. vein of smaltite was opened.——The November output of the Nipissing from four shafts amounted to $200,851, of which $84,000 came from the Fourth of July shaft alone. The ore reserves were increased during the month.——The Floyd Mining Co., of Cobalt, and the Otisse-Currie, Elk Lake, have gone into liquidation.——Cripple Creek, situated about 45 miles south of Porcupine, is again attracting attention. Some good work has been done recently, and the reports of high assays of the ore taken out have been received.——The Preston claim, south of the Dome in Porcupine, and adjoining the Foster, is reported to have changed hands for $250,000.——Work on the extension of the Temiskaming & Northern Ontario Railway to Porcupine is being pushed as rapidly as possible.

In accordance with a resolution adopted by the Mines Committee of the Canadian House of Commons in favor of the codification of the mining laws, a deputation of the Canadian Mining Institute December 14 waited on the Premier, Sir Wilfred Laurier, and other members of the cabinet at Ottawa, urging them to take action. It was arranged that an act should be prepared and presented to Parliament, codifying the existing Federal laws with respect to mines, and that action should be taken to secure uniformity of legislation throughout Canada.——Dr. F. D. Adams, of McGill University, Montreal, was chosen president, and Director R. W. Brock, of the Canadian Geological Survey, secretary, of the International Geological Congress at a meeting of geologists and mining men held in Toronto on December 2. The Congress will hold its triennial session here in 1913, and the rule is that the country in which the congress meets shall elect the officials.

DEADWOOD, SOUTH DAKOTA

New Ore-Shoot in Golden Reward.—Mill of Wasp No. 2.— Proposed Smelter for Galena.—The Tinton Mill.—Other Black Hills News.

By the opening of a shoot of ore southeast of any previously known orebody in its ground, the Golden Reward company has added much to its probable productive area in the Bald Mountain district. The shoot is over 1000 ft. long, nearly 300 ft. wide, and 10 to 14 ft. thick. The ore is soft, and contains a high percentage of sulphur and iron. It can be cheaply mined, roasts easily to a perfect cyaniding material, and, if mined in the quantities contemplated, can be transported to the mill at Deadwood at 25c. per ton. It is understood that the C. B. & Q. R. R. Co. has made this rate for 500 tons daily, which is the tonnage the Golden Reward company expects to produce as soon as the roaster and mill are equipped. It is planned to build the roaster at the mine and increase the capacity of the 200-ton cyanide mill at Deadwood to 500 tons daily. The ore-shoot referred to has been tapped from both the Mikado and Union shafts, and development on it is in progress.——The Wasp No. 2 company's new cyanide mill has been started, its former mill having been destroyed by fire last January. The new mill was carefully designed, and is a model dry-crushing cyanide plant of 400 to 500 tons daily capacity. The ore, received from the mine in 5-ton skips, is dumped into a bin above a No. 6 Gates crusher, by which it is reduced to 1½ in., is elevated, passes over a ¾-in. grizzly, then to two No. 4 Gates crushers, reducing to ½-in. size. The ore is then dropped into the crushed-ore bin, and is fed by shaking feeders to four 16 by 36-in. McFarlane rolls—two used as cracking rolls and two as finishing rolls. The finished-ore bin has a capacity of 750 tons, and the ore is charged into six 14 by 32-ft. leaching tanks by a system of six individual conveyors, fed by a conveyor carriage traveling parallel to the ore-bin. Precipitation is accomplished in three steel zinc-boxes. The mill is operated throughout by electricity, supplied by the Consolidated Power & Light Co. of Deadwood. A total of 386 hp., in motors, is installed in the plant. The plant was started on December 1, and up to date has operated satisfactorily.——It is announced that Chicago capitalists have become interested in building a smelter in the Galena district. The proposed plant will contain several of the devices of Paul Danckwardt, one of the pioneers in pyritic smelting in the Black Hills. The principal supply of pyrite will be obtained from the Gilt Edge-Maid mine, where a big body of low-grade concentrating ore was developed last summer. ——Placing the concrete lining in the tunnels of the Homestake hydro-electric plant on the Spearfish river is in progress. The entire 22,000 ft. of 7 by 9-ft. tunnel will be lined to reduce friction and eliminate timbering. Work is also in progress upon the diverting dam and intake. It is expected that the plant will be running by July 1, if there is no delay in the delivery of machinery.——The

Tinton mill, near Nigger Hill, has been shut down for the winter, after a summer devoted largely to experimental work in the mill, and further development of the mine. A large quantity of high-grade cassiterite concentrate was produced during the season and shipped to Swansea, Wales. The mill work was satisfactory, and plans for the coming summer include enlarging the plant and remedying a few defects. The mine is developed to supply a large tonnage, and with tin commanding the present high price, the company is much encouraged in its work.——P. H. Bertschy, who is leasing on the Imperial, at Portland, is shipping his output to the Lundberg, Dorr & Wilson mill, at Terry. The Imperial company recently let a contract for 250 ft. of cross-cutting from the bottom of its shaft. This shaft, which was sunk three years ago, penetrates the lower quartzite of the Cambrian, but several thousand feet of work from the bottom failed to find ore. It is stated that the company intends to thoroughly explore for ore from the bottom of the shaft, and that the present contract is but the beginning of what may be anticipated during the coming year.——The Portland company recently purchased the Ajax ground, adjoining the original holdings of the company on the north. The Portland previously purchased the American Eagle, at sheriff's sale, and the Frawley ground, adjoining on the west and north. This gives the company a large area of nearly virgin ground, as well as an excellent mill, which is now undergoing repairs and remodeling, and which is to be started in the spring.

NEW YORK

The Granby Dividend. — Improved Condition of the B. C. Copper Co. — Mill Equipment at Chino and Ray. — The Mines Company of America.—Camp Bird and Santa Gertrudis.

Of the funds recently raised by the A. S. & R. Co., $1,000,000 is to be expended in the betterment of the plant at Baltimore. The Guggenheim forces are assuming the aggressive, not only in the development of copper properties, but in the struggle for supremacy among the smeltermen.——There is some criticism of the Granby dividend. In view of the fact that the life of the Granby is inconsiderable, unless there are discoveries of new orebodies, and that the newly optioned Hidden Creek property will require considerable development before its worth can be determined, it appears that a distribution of any material part of the cash on hand is hardly justifiable. The British Columbia Copper Co. is making a strong effort to improve its position. Some $300,000 has been accumulated as a dividend fund. The cyanide plant at the Napoleon mine, the aerial tramway at the Lone Star, and the enlargement of the furnaces at Greenwood have all been paid for, and the taking over of the Dominion property is practically accomplished. The management states that earnings will show 15% net, and that early in 1911 the company will probably begin distribution on a 12% basis. ——It was originally planned to equip Chino with a 3000-ton concentrator; but present plans contemplate a capacity of 5000 tons. The capacity of the plant on the Ray Consolidated is to be almost doubled. It is one of the incongruities that announcements of this nature must accompany the news of renewed efforts to cut down production. Some of Thos. W. Lawson's enemies have declared many times that no corporation upon which he ever laid hands prospered. Mr. Lawson has as many times argued the question and pointed with pride to what he accounts his triumphs in the way of promotions. His enemies scored again, however, in the recent shut-down of the Balaklala, now controlled by the First National Copper Co. The directors are addressing the stockholders, suggesting the exchange of First National stock for shares in the Aztec Petroleum Co. on a basis of one share of the former for one and a half of the latter. The Aztec Petroleum Co. has lands in the Coalinga oilfield.——The Mines Company of America has resumed paying dividends on a basis of 9%, 22½c. per share quarterly, which is equal to 18% on the present selling price. This company is absorbing the Dolores, El Rayo, both in Chihuahua; the old Mines Company, at Minas Prietas in Sonora; and has recently bought the La Dura. The right to exchange stock expires on January 11, 1911, but so large a proportion has already been converted that the merger is now practically complete.——The Ely Central Copper Co., recently in the limelight by reason of the manipulation of its stock by B. H. Scheftels & Co., was sued by William Bullock Clark, of Johns Hopkins University, on a contract under which Clark was to examine the property and be paid in stock. The contract was broken, and the examination was not made; Clark sued for the value of the stock, at the time of the breach of the contract, and recovered judgment in the Federal Court for $72,966.——The annual report of the Camp Bird shows larger earnings than for any previous year in the company's history. The gross production was $2,720,000. The ore reserves of the mine have for some years been the one critical question, though there never has been a time within the last four years when there was as much as six months supply of ore in sight.——Speaking of the Santa Gertrudis, the company's chairman says: "The Camp Bird has done well for us for nearly nine years, and I may say that the Santa Gertrudis mine prospects are better than when we first brought out the Camp Bird. The engineers report reserves in the Santa Gertrudis of 462,000 tons on December 20, 1909; the net profits from these reserves should be approximately $4,620,000."

Frank Lewis, of Colonia Juarez, has sold his mine, situated near Dos Cabezas, to Juan Terrazas at $70,000. The purchaser holds an option on another mine belonging to Lewis and others.

TEXAS

Mine Development in Llano District. — Tin Mining and Concentrating at Mount Franklin.

Attention on the part of practical mining men is being attracted to the mineral region around Llano by the success of the Llano Gold Mining Co. in the development of its property, situated a few miles from that place. Work has been in progress for the last three years exploiting this mine, and the results of development, apparently, have justified the erection of a 50-ton reduction mill. Such a mill will soon be finished and placed in operation. It is so planned that its capacity may be increased to 200 tons when the ore output has become sufficient to justify the addition to the plant. The company has expended more than $100,000 in development which was carried on to determine the location and extent of the orebody. It is announced by McCarty Moore, manager for the company, that the main lode has a width of 28 ft., between well defined walls; that the ore is partly free milling, and that average samples taken across the vein assay $15 per ton in gold. The workings have a depth of about 600 ft.——Some development work is being done on the tin mine, situated on the east side of Mount Franklin, 15 miles from El Paso. The mill on the property is in operation, turning out about 50 tons of concentrate, running from 60 to 65% tin, every 24 hours. The concentrate is smelted in the furnace which is operated in connection with the mill. The tin product is shipped to Philadelphia, in pigs of 100 lb. each. There are eight veins of tin upon the property which are now being developed.——J. Heard and associates are developing a claim, situated 42 miles northwest of Toyah and 10 miles north of Boracho, in the foothills of the Guadalupe mountains. The work so far done indicates that a body of good ore will soon be uncovered. It is stated that the ore runs from 40 to 60% zinc, 5% iron, and a trace of silver and gold. It is planned by the owners to erect a concentrating mill as soon as development operations have progressed a little further.——Ore shipments were recently begun by Eagle & Walker from their mine near Alamore, in the trans-Pecos region. The ore contains gold, silver, and copper.

General Mining News

ALASKA

(Special Correspondence.)—The Jumbo mine, at Sulzer, has made another shipment of ore to the Tyee smelter at Ladysmith, B. C.——There is about 2000 tons of gold ore blocked out in the Goldstream mine, and A. A. Wakefield, the superintendent, is preparing to make a small shipment.——Operations at the It mine have been suspended for the winter.

Ketchikan, December 8.

(Special Correspondence.)—The Alaska Industrial Co., owner of the Sulzer mine, on Hetta inlet, Prince of Wales Island, made 21 ore shipments to the Tyee Copper Co.'s

Sulzer Mine, Alaska.

smelter at Ladysmith, B. C., during the year 1910, aggregating 15,000 tons. Within the same period 25,000 tons was mined. In the meantime, the property has been equipped with a Sullivan duplex air-compressor and 11 drills of same make. In the work of exploring the ore-bodies with diamond-drills, 38 holes were drilled, in each of which ore was found. The drill-hole made from the floor of the lowest level showed the ore to persist to a depth of 200 ft., the better grade being at the bottom. The plan now is to drive lower adits which will open the mine 500 ft. deeper. Chas. A. Sulzer, general manager for the company, states that such adits are to be driven during the year 1911. The company has been mining and shipping continuously since 1906, and now contemplates operating on a larger scale than heretofore. It has a hydro-electric plant, supplying power for all purposes, a 9000-ft. aerial tramway that extends from the wharf to the mine. The ore consists principally of chalcopyrite, in a gangue of epidote, garnet, feldspar, and limestone, carrying copper, magnetite, gold, and silver.

Sulzer, December 15.

The report of the Alaska Mexican Gold M. Co. for the month ended November 15, is as follows: Mill time, 31 days. The 120-stamp mill ran 29 days, 5 hr., 31 min.; water-power, 10 days, 19 hr., 12 min.; steam-power, 18 days, 10 hr., 19 min. Ore crushed, 18,184 tons; concentrate saved, 300 tons. Estimated gross value of free gold recovered, $23,520.70; estimated gross value of concentrate, $22,614. Total production, less $2026.12 due Alaska United G. M. Co., $44,108.58; realizable value, $42,673.38. Operating expense, $31,126.41; net operating profit, $11,546.97. Construction expense, $4843.57; yield of ore milled, $2.42 per ton. Stock of broken ore, 8046 tons. Development work, 241 ft. in ore, 268 ft. in waste; assay value of ore, $2.70 to $3.62.

The report of the Alaska United G. M. Co. for the month ended November 15, was as follows: Mill time, 31 days. Ready Bullion 120-stamp mill ran 30 days, 11 hr., 41 min.; water-power, 21 days, 15 hr., 54 min.; steam-power, 8 days, 19 hr., 47 min. Ore crushed, 20,440 tons; concentrate saved, 371 tons. Estimated gross value of free gold, $24,526.04; estimated gross value of concentrate, $17,801.59; gross realizable value, $40,596.45. Operating expense, $26,533.23; net operating profit, $14,063.22; construction, $3300.79. Yield of ore milled, $2.07. The 700-Ft. Claim 100-stamp mill ran 28 days, 21 hr., 35½ min.; water-power, 9 days, 3 hr., 13 min.; steam-power, 19 days, 18 hr., 22½ min. Ore crushed, 16,239 tons; concentrate saved, 280 tons. Estimated gross value of free gold, $21,047.15; estimated gross value of concentrate, $16,603.23. Estimated realizable value, $36,-333.40; operating expense, $25,882.85. Net operating profit, $10,450.55; construction, $2491.93. Yield of ore milled, $2.31 per ton. Development work on Ready Bullion claim, 326 ft. in ore, 6 ft. in waste; on 700-Ft. Claim, 168 ft. in ore. Assay value of ore, $0.64 to $5.85 on former, $3.93 to $5.15 on latter claim. Stock of broken ore, 2440 tons on Ready Bullion, 6800 tons on 700-Ft. Claim.

Fairbanks lost nine buildings by fire on December 15, valued at $120,000. While the fire raged, mercury thermometers showed a frigidity of 50 degrees below zero.—— It is reported at Cordova that G. T. Nichols and associates have purchased the Walker-Erickson group of partly-developed claims in McKinley lake district, on which development will be continued this winter. The property was sold by B. W. Walker, Tim Erickson, E. S. Malone, and Sam Erickson, who have kept up development for the last three years. They had 200 tons of high-grade ore on the dump at the time of the sale.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The starting of the Miami Copper Co.'s new concentrator, which will be the initial treatment of the low-grade ore in the Miami district, is being awaited with much interest, but it hardly seems likely that its operating can begin on January 1, as announced. The pumping station at Burch is about completed, but there remains over 9000 ft. of pipe to be laid and connected at the concentrator before the plant can be put in operation. The cooling-tower, west of the power-house on the flat north of the Miami townsite, is assuming shape. In the concentrator building the crushing machinery, Deister slime and sand tables, and the electric motors to operate them, are all in position; a force of men is putting in the shafting and arrangements for placing the switchboard. The six 250-ton tanks for handling the concentrate have been finished. Work has been started on the tramway that will be used to haul supplies from the railroad at Miami to the concentrator and mines on the hill. Up to this time all material and supplies have been transferred from the railroad to the tramway built in the canyon southwest of the main works; and the erection

of the dam across the mouth of this canyon will make it necessary to remove the track and buildings from this place, as the company is to use this canyon for the mill tailing. In the underground workings about 80 men are kept busy getting ready for such production as will keep the concentrator supplied with ore after it is started. In the main drifts the timbers are being strengthened and arrangements made for the stringing of the trolley wires for the electric system that will be used for hauling ore to the bins at the bottom of the main shaft. The work on the raises under the ore 'rooms' on the 370-ft. level is in progress, and these raises are being provided with chutes, through which the ore is to pass to the 420-ft. level, where the main haulage system is installed. The three churn-drills which are being operated in the northwestern part of the Miami ground, to determine the extent of the orebody in that direction, are sinking at an average rate of 35 ft. per shift of 12 hours each.

Globe, December 27.

CALIFORNIA

CALAVERAS COUNTY

The 500-ton concentrator and the smelting plant of the Calaveras Copper Co. are expected to be in operation soon after the first of the year.

ELDORADO COUNTY

The Pacific mine, situated within the limits of Placerville, has new orebodies in five different veins at the 500-ft. level, and it is announced that a new mill is to be built on the property, and that the present force of 60 men is to be greatly increased.

INYO COUNTY

The report of the Skidoo Mines Co. for November 1910 shows 1317 tons of ore milled; value of bullion produced, $21,335.89. The operating costs were $7585.66; expenditure for development, $470.20; net profit for the month, $13,280.03.——The Benton cyanide plant is now in operation on tailing from old mills. The Benton properties are in the hands of Remington, Cahoone, Musser, and their associates.

NEVADA COUNTY

Wm. McLean & Co., operating the Republic mine, at Graniteville, have performed a great deal of development work, the latest labor having resulted in opening the vein on the lower adit level.

PLUMAS COUNTY

The Jamison M. Co. is employing 50 to 60 miners blocking out ore and developing. The stamp-mill, which had been inactive two months by reason of the lack of power, was started again last week. The property is situated near Quincy, and is a dividend payer.

SHASTA COUNTY

The Balaklala Copper Co. closed its smelting plant at Coram on December 15, as the result of the demands made by Shasta County Farmers' Protective Association, but it is reported that notice was posted later by R. T. White, the manager, to the effect that the smelter would resume operating on December 28. It is understood that additional apparatus for perfecting the Cottrell system of controlling the smoke and fume is being installed.

SIERRA COUNTY

F. M. Phelps and associates have had a force of miners at work 18 months on the Monte Cristo gravel mine at Downieville, who are now driving on the Belcher channel, in which it is expected soon to open the pay-streak. This shoot on the Belcher proved profitable. The Twenty-One mine, situated at Alleghany, has been opened by an adit on the lode which has a width of 5 to 7 ft.; the ore, assaying $7 to $135 per ton, is mostly free milling. There is close to 900 ft. of stoping ground in the vein above the adit, which is to be extended 200 ft. farther. This lode is the same as that of the Tightner. The Red Star mine, which is said to have the same vein, has an adit 50 ft. in rich ore.

SISKIYOU COUNTY

The Mono mine, 6 miles west of Yreka, was recently sold to Eastern investors represented by R. M. Wade of Chicago. The vendor was the Mono M. Co., for which R. E. Newcomb had been manager. The property is considerably developed from a 550-ft. shaft, and is said to have a 4-ft. vein of ore assaying $15 per ton. The purchasers intend to operate the mine with a larger force than that heretofore employed.

TRINITY COUNTY

(Special Correspondence.)—The 200-ton cyanide plant of the Trinity Gold Mining & Reduction Co., near Carrville, has been in operation ten days, and is giving the best of satisfaction. The ore is delivered to the crushing plant in trains of two-ton cars where it is crushed to 1-in. size by a Blake crusher. It is then distributed to the battery ore-bins by two belt-conveyors with an automatic reversible tripper. The battery bin has a capacity of 1300 tons. The ore is fed to the 8 five-stamp batteries, weighing 1050 lb., by improved Challenge feeders, and is crushed in cyanide solution through 30-mesh screens. The ore averages $5.25 in gold and silver, and 80% extraction is made by amalgamation. A 2-lb. cyanide solution is used. The pulp passes direct from the batteries to four 48-in. double hydraulic cone-classifiers; the sand passing to four 30 by 7-ft. leaching vats, to which it is fed in rotation and distributed by means of a Butters distributer. The slime is thickened in two Dorr thickeners, and a pulp of one-to-one consistence is diluted to three to one with barren solution and then agitated in two Pachuca agitators for three hours. It is then discharged into two other 12 by 25-in. Dorr thickeners; the thickened pulp, of a consistence of two to one, being fed to two Oliver continuous filters, from which it is washed and discharged from the mill. The overflow from the thickeners, leaching-tanks, and Oliver filters is run to clarifying-tanks, where the solution is clarified before precipitation by the Merrill system; the barren solutions, rarely running over 3c., are built up to the requisite strength and pumped back to the storage tank for use again in the batteries. This is one of the most up-to-date cyanide plants in the State. The machinery is all electrically driven, the power being supplied at the company's plant, which consists of a Francis turbine, direct-connected to a 400-kw. generator. The voltage is 4000, 3-phase, 60-cycle, which is transformed at the mill down to 440. Water is taken from Coffee creek by a 3 by 4-ft. flume, 9000 ft. in length, which will deliver 4000 cu. ft. of water per minute under a 107-ft. head at the power-house. The company is employing 60 men and has laid in extensive supplies and prepared to run during the winter. The property is well equipped with boarding-house, kitchen, dining-room, stables, and storehouse. The orebody has been stripped over a surface area of three acres, with hydraulic giants, and mining is done by the glory-hole system, except during stormy weather, when inside stoping will be resorted to. Air-drills are used, and ore is being delivered to the crusher at about 40c. per ton. When the mine is opened up better, it is expected to reduce this mining cost to 30c. per ton. The orebody varies in thickness from 40 to 90 ft., and some 400,000 tons of ore averaging $5.25 in gold and silver is now exposed.

Carrville, December 23.

TUOLUMNE COUNTY

(Special Correspondence.)—The New Aurum Mining Co., of which Jacob Ross is president, holds under bond the New Era group, and is planning for future operations of the mine and 10-stamp mill. The New Era and War Eagle adits, now in about 250 ft., will each be driven an additional 100 ft.; and that on the Hardtack claim, which is in 115 ft., will be extended about 50 ft. It is expected that when this work is done, enough ore will be accessible to enable the company to keep the mill in continuous operation. Only slight repairs are needed to put the mill in good working order. W. T. Carter, owner of the property,

is superintendent.——An 8-in. vein of rich ore has been discovered near the Riverside mine by Rufus George. Development work is in progress.——The Densmore mill will be started in a few days on the 100 tons of ore in the bins.——Work is to begin soon at the Lucky Jack mine, in the Basin district. The property is developed by a long adit which shows a vein of good-grade ore, with some rich specimens.——The Contention mine, near Columbia, was recently sold to A. B. Dodd, of San Francisco, and S. J. Silva, of Oakland.——Development work is being done at the Telegraph Line mine, below the Mohican, and rich ore is being uncovered.——An electric-power transmission line has been constructed from Tuttletown to Melones.—— It is said an Eastern syndicate has purchased the holdings of the Tuolumne River Power Co., paying therefor $665,000. According to the report, Lester R. Wiley retains his interest in the new concern and will continue as manager. ——A three-fourths interest in the Oakland mine, near Columbia, has been sold by J. W. Pitts to E. J. Hastings, Leander Miller, and Charles Bryant.——The Santa Ysabel mine, formerly operated by Boston people, has passed to the control of a new company whose principal stockholders are said to be San Francisco men. Local people are also interested. It is understood that operations are soon to be resumed, and that the terms of the bond call for 800 ft. of sinking and 1000 ft. of driving within two years. ——Several of the pocket mines on Baid mountain, northeast of Sonora, have yielded heavily during the last few weeks, among them being the Birney, operated by W. H. Rehm, C. D. Elsbree, and R. and L. Fulcher; the Lewis, worked by William Lewis and William Sullinger; the Stewart, operated by D. Newman and J. Parr; and the Garrett and the Sugarman. The aggregate production in the time stated is reported to be approximately $25,000. ——High-grade ore has been uncovered at a depth of 140 ft. in the Anaconda mine, north of Columbia; it is owned by John O'Hara and A. McKenzie.——Machinery for a 10-stamp mill is being taken to the Contention mine, recently sold to an Eastern company. A large quantity of lumber and timbers is also being hauled to the property. ——Operations have been discontinued at the Longfellow mine, at Big Oak Flat.——Some changes are contemplated in the Dutch mill, in which the present stamps will be replaced by 1000-lb. stamps. It is reported that the Big Casino Mining Co. will resume work at the Mack mine early in January.

Tuolumne, December 26.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A force of carpenters is at work at the Santiago mine constructing bunk-houses, to provide for a working force of 100 men by January 1.—— Shipments of ore will be started soon from the Big Indian mine. Stoping has been commenced on an 8-in. vein of ore that is worth $70 per ton in gold and silver. ——H. B. Clifford & Co. have awarded a contract to A. Friedman to drive on the Bellman vein. Work will be carried on through the central adit. The same operators will also work through the Newhouse adit.——Brauch & Son, leasing on the Yellowstone vein through the Lucania adit, uncovered a 4-ft. vein of ore that is worth from $15 to $55 per ton in gold and silver.——Work was resumed last week on the Dorit property, the vein in which is being sampled; some of the stuff was found to assay $12 to $14 per ton.——A carload of smelting ore was shipped last week from the Kinda mine on Bellevue mountain, the ore having assayed 2.30 oz. gold and 16 oz. silver per ton. G. F. Crawford, of Kansas City, Mo., is owner.——Andrew Anderson is working on the Victor mine at the head of Virginia canyon. Shipments will begin during the next two weeks.——G. W. Ford, holding the German mine under a five years' lease, has commenced development. A shaft is to be sunk to a depth of 200 ft.——The adit on the Centennial vein, the portal of which is at the head of Rose street in Georgetown, is being driven ahead. It is stated that a body of medium-grade ore 10 ft. wide is being followed that is worth $14 per ton in gold and silver.

Georgetown, December 24.

LAKE COUNTY

The part of Leadville district known as Big Evans gulch is drained to a depth of 850 ft. by the Yak tunnel, and operators who are doing deep mining there have to pump water up to that level only. The Resurrection shaft No. 2 has reached a depth of 150 ft. below the Yak level, and electric pumps are to be installed at the 1000-ft. station. It is stated that the Yak company has sunk 600 ft. below the tunnel-level in Cambrian quartzite, the result having been to open big bodies of ore from which regular shipments are being made.——The Climax, on Fryer hill, has been leased to M. L. Buchanan and others, who opened a 3-ft. vein of lead ore in the course of their development to find zinc-carbonate.——The Western M. Co., operating on Carbonate hill, has put the Adams shaft in working order. It will be used as the hoisting shaft for the properties being worked by this company. In the meantime the Wolftone shaft will be newly timbered. This company is developing vigorously for zinc-carbonate ore.——Lessees on the Lafayette group, at the head of Big Evans gulch, expect to further develop the property by driving a deep adit toward Iowa gulch, the expectation being to intersect fissure veins known to exist in that part of the district.—— The Alps-Aztec group, on Little South Evans, has been opened to some extent by an adit starting on the hillside; it is to be further developed by sinking a 250-ft. interior shaft at a point near the face of the adit. A station is then to be established at the bottom of the shaft, and exploring for ore started from that place.

IDAHO

BOISE COUNTY

The Boise King Placer Co. has acquired 480 acres of placer ground on the middle fork of the Boise river, which, according to certain tests, has a depth to bedrock of 40 ft., and contains an average of 20c. gold per cubic yard. An ample supply of water can be brought in ditches and pipes to the tract at good pressure, and it is announced that a number of hydraulic giants will be brought into use next season.

LEMHI COUNTY

The Leesburg placers, which were worked profitably in early days, are to be dredged for gold next season by Busby and Mullins. There is an area of 150 acres here which it is believed can be dredged profitably.——The Kirtly Creek Gold Dredging Co., concerned in which is John Martin, of Ross, California, has purchased a tract of placer ground on Kirtly creek, five miles from Salmon, and it is announced that a dredge is to be built and put in operation there next summer. Mr. Martin and associates have prospected and tested the ground.

NEVADA

STOREY COUNTY

The stockholders of the Ophir Silver M. Co. met in San Francisco on December 20, at which the old board of directors, consisting of the following members, was re-elected: Franklin Leonard, Charles Hirshfield, B. F. Shaw, Geo. S. Sturges, A. F. Coffin, Herman Zadig, W. J. O'Connor. Thos. F. McCormick was re-elected superintendent. The superintendent's report, for the year ended November 30, showed that 9410 tons of ore was concentrated in the Kinkead mill, the gross assay value of which was $210,451.24; of this $151,401.49 was gold, and $59,049.65 was silver. The yield per ton averaged $22.36. Besides, there was sold to the Charles Butters company 1637 tons of ore of an average value of $24.65; mill tailing sold to the latter company brought $5842.37. The principal mining operations of the year were on the 2000, 2100, 2200, 2300, and 2400-ft. levels.——The report of Whitman Symmes, superintendent for the Ward Shaft Association, for the year ended November 30, accounted for the reconstruction of the shaft from the 2295 set to 15 ft. below the 2475-ft. station; a station was cut at 2000 ft., and from this place

100 ft. of driving was done toward the Gold hill workings; a station for three pumps was cut from the 2100-ft. station. The establishment of a station at 2450 ft., and driving commenced in the direction of the Combination shaft, are noted; also the cutting of a pumping station at 2475 ft., where pumps are being installed. When the latter pumps are in operation the plan will be to drive from the 2475-ft. point to effect drainage of the Combination ground. The improvement of the ventilation of the Ward shaft workings is also reported.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Socorro mines yielded 27,700 troy ounces of silver and gold, and a large amount of concentrate from a little in excess of 3000 tons of ore milled for the month. From 20 to 30 stamps are dropping. Representatives of the Leyner company are here making competitive tests with other drill-makers.——The plant of the Ernestine M. Co. is being operated successfully. Last week 708 tons of ore were treated, the return from which was 56 sacks of high-grade concentrate, in addition to precipitate taken from the zinc-boxes.——In the Deadwood mines, cross-cutting on the 500-ft. level showed the vein to be 18 ft. wide. The pipe-line for water-supply is finished, and the mill is to be ready to start operating in January.——The Mogollon Gold & Copper Co. is building an assay laboratory and machine-shop, both of which will be finished soon. Surveys are being made to determine location for the hoist and millsite.——The Oaks company is developing a number of properties which it holds under option.

Mogollon, December 23.

OREGON

JOSEPHINE COUNTY

The Alameda M. Co., which recently completed its smelting plant, has deferred blowing in its furnace until the auto-truck road is finished from Leland to Alameda, when coke can be hauled in more cheaply. Wagon-roads have been made nearly impassable by heavy rains. The Allen mine, adjoining the Alameda, was sold recently to the Alameda company by the Standard Metals Co. of Portland. These mines and the smelter are in Galice district.——The Oriole mine is well developed and equipped. Adit No. 4 is being driven to cut the lode at a depth of 900 ft. It has been advanced 700 ft. and it is expected to reach the vein 200 ft. ahead. A car of ore recently shipped to Tacoma sampled $204.20 per ton.

UTAH

JUAB COUNTY

The Centennial-Eureka M. Co. has electric-driven pumps which are lifting 1000 gal. of water per minute from the 2200-ft. level. The mine is dry down to the 2100-ft. level. ——Work at the Eagle & Blue Bell mine, at Eureka, is in charge of William Owens. The new shaft has stations at 700, 800, and 900-ft. points, from which levels have been driven to the orebodies. Ore being shipped is mined on the 800, 1100, and 1200-ft. levels.

SALT LAKE COUNTY

The North Utah M. Co. is preparing to operate the Redwing mill, situated at the mouth of Markham gulch, Bingham district, as a custom plant. It will be in charge of H. F. Widdicombe, and a beginning is to be made on lead ore from the Yampa mine. The plant has been partly reconstructed and newly equipped, and has the capacity of 200 tons per day.——The Brooklyn mine, belonging to the Bingham Mines Co., has a 12-ft. body of lead ore, which was opened by driving a winze from the 1600-ft. level. A station has been cut at the base of the winze and driving will be started in ore. The mine is in Upper Car Fork, Bingham district.——The Bingham-Newhaven company paid a dividend of 20c. per share this month, amounting to $45,800.

SUMMIT COUNTY

The Daly-Judge M. Co. has gained access to the 1600-ft. level in its Park City mine. This level was submerged for a number of years, and has been unwatered by pumping, supplemented in the last few weeks by a connection of this level with the Daly West drainage system.——The Silver King Coalition Co., under the superintendence of George D. Blood, has applied electric haulage to the 1300-ft. level and the Alliance adit level, which nearly completes the electrification of the property.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The Ikeda Mines, Ltd., of Vancouver has taken a bond on the property formerly operated by a Japanese company, situated on Moresby Island, of the Queen Charlotte group, 500 miles north of Vancouver. The property was considerably explored during last summer by diamond-drilling and other underground work, and it is now decided to proceed with development and mining ore. The ore occurs as oxides and sulphides of iron and copper, carrying gold and silver, in lenticular masses. The Japanese mined only the high-grade ore, but the company now in control intends to equip the mine in such a way as will enable it to work the low-grade ore and mine a large tonnage. The work is under direction of Andrew G. Larson, consulting engineer.

Vancouver, December 14.

CENTRAL AMERICA

NICARAGUA

(Special Correspondence.)—The Babilonia mine, situated in La Libertad mining district, has been sold by J. M. Hall, G. L. Carlisle, and J. Santos Zelaya to the Oroya Exploration Co., of London, which has been operating the mine during the last 18 months under a limited option. J. A. Willey, who was manager during that period, did 5000 ft. of development and obtained enough revenue to pay all expenses of development and operating by milling ore in a single pneumatic-stamp mill. The mine is on the mother lode of the district.

Managua, November 30.

MEXICO

CHIHUAHUA

La Republica Mining Co., operator of the Republica mine and mill in Rayon district, reports 1140 tons of ore crushed for November, the value of metals extracted amounting to ₱83,131 the operating costs were ₱51,605, the capital expenditure having been ₱4689. J. Gordon Hardy is consulting engineer; the office of the company is at El Paso.——The regular quarterly dividend of 2% has been declared by the Rio Plata Mining Co., payable December 29.

SINALOA

The Mazatlan smelter concession has been purchased by the Pacific Smelting & Mining Co., which owns the plant at Fundicion, Sonora, and, through one of its subsidiaries, the smelter at Guaymas. It is announced by Courtenay De Kalb, the general manager, that a large reverberatory plant is soon to be erected at Mazatlan.

SONORA

The Mexican-American Smelting & Refining Co., which owns the smelter at Guaymas, is to install a Huff electrostatic plant for cleaning up the zincky concentrate of the west coast, thus avoiding the penalty on zinc for the shipper, and enabling him to sell the zinc concentrate, charging to it the milling costs and brokerage for marketing. Courtenay De Kalb, the president of the company, states that the lead bullion produced probably will be shipped direct to Antwerp; that the coke supply will be obtained partly from Australia and partly from China. The company has 4000 tons of ore now in its yards and is ready for business. The same company has purchased the Southern Pacific lead-silver mine, at Tesia, near Navajoa. The Pacific Metallurgical & Refining Co., whose principal plant is at Fundicion, has purchased the Morismenia copper-gold mine situated close to Navajoa. George W. Dean, of St. Louis, has become superintendent of the Guaymas smelting plant.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

QUALITATIVE CHEMICAL ANALYSIS. By J. I. D. Hinds. Pp. vii + 266. Index. Chemical Pub. Co., Easton, Pa. Price $2.

A new treatise on qualitative analysis from the standpoint of ions, solubilities, and mass action. It preserves all the features and excellence of the old methods, while introducing the student to the newer view of chemical activities and recent explanations of analytic reactions and phenomena. It contains many tables which aid and simplify the work of qualitative determinations.

RICHARDSON'S MANUAL OF MEXICAN MINING LAW. By D. A. Richardson and Frank W. Doan. Pocket edition. Pp. 382. Index. W. H. Courtright, Denver. Price, bound either in buckram or flexible black leather, $3.

This little volume on the mining laws of Mexico is the latest publication devoted to this important matter. There have been numerous changes in the Mexican laws regarding the acquisition of mining property in that republic, and Richardson's Manual is right up to date. It contains all the statutes pertaining to corporations, mines, and mining in Mexico, in effect in 1910. The work is in English and contains an excellent Mexican-English vocabulary of words most commonly employed in mining business in Mexico. The various blank forms in use in Mexico in mining transactions are given in both English and Spanish, which makes the book particularly useful to those unfamiliar with Spanish.

ROCK-DRILLS. DESIGN, CONSTRUCTION, AND USE. By Eustace M. Weston. Pp. 367. Ill., index. McGraw-Hill Book Co., New York. Price $4.

This is a most interesting and useful book on a subject important to every miner, whether superintendent, drill-runner, or chuck-tender. It describes the evolution of the rock-drill, through its many phases, from the novel but comparatively inefficient machines first introduced, to the highly efficient devices of the present day, including all types, from the small, light hammer-drills to the heavy 'sluggers' employed in railroad tunneling. The various electric and rotary-drills are also described. The chapters on high explosives, rock-drilling, blasting, and maintenance of rock-drills are of great value, as well as those on drifting, stoping, and shaft-sinking. Mechanical drill-sharpening machines and their use are described, which adds value to a thoroughly practical treatise by a practical man—one who has himself run various rock-drills and learned their usefulness and present limitations.

The Prospector

PAPERS AND REPORTS RELATING TO MINERALS AND MINING IN NEW ZEALAND. By Roderick McKenzie, Minister of Mines. Pp. 138. Ill., maps, index. Wellington, N. Z., 1910. The annual report of the Minister of Mines for 1909.

A PROPOSED CLASSIFICATION OF PETROLEUM AND NATURAL-GAS FIELDS, BASED ON STRUCTURE. By Frederick G. Clapp. From Economic Geology, Sept. 1910. Lancaster, Pa. Describes the occurrence of oil and gas under varying geological conditions.

THE NATURAL CLASSIFICATION OF IGNEOUS ROCKS. By Whitman Cross. From Jour. Geol. Soc., Aug. 1910. Pp. 36. Discusses the various bases of classification of igneous rocks, and advises an arbitrary classification, as natural boundaries do not exist.

NORTH DAKOTA LIGNITE AS A FUEL FOR POWER-PLANT BOILERS. By D. T. Randall and Henry Kreisinger. U. S. Bureau of Mines. Bull. 2. Pp. 42. Ill. Washington, 1910. Results of numerous tests show that this fuel, though low grade, may be used economically under boilers that generate their full-rated capacity of steam—all of which makes for conservation of the most practical character.

CONTRIBUTIONS TO ECONOMIC GEOLOGY, 1908. PART II. MINERAL FUELS. By M. R. Campbell and others. Bull. 381, U. S. Geol. Surv. Pp. 559, Ill., index. Washington, 1910. This volume contains numerous interesting and valuable papers, many of which have been separately issued in advance. It is striking, none the less, that the geologists working on coal are apparently just a year behind their fellows who have been studying ore and whose report for 1909 is being distributed at the same time as is this.

CONTRIBUTIONS TO ECONOMIC GEOLOGY, 1909. By C. W. Hayes, Waldemar Lindgren, and others. U. S. Geol. Surv. Bull. 430. Pp. 653, Ill., index. Washington, 1910. This is the eighth in the series of annual volumes that began with No. 213 in 1902, and is a most useful report. In it may be found short articles giving in condensed form the main results of the investigations carried on in 1909, except those covering fuels and Alaska, for which companion volumes are to be issued. Among the longer and more notable papers in Bull. 430, are 'The Occurrence of Copper in Shasta County, California,' by L. C. Graton, and 'Preliminary Report on the Phosphate Deposits in Southeastern Idaho and Adjacent Parts of Wyoming and Utah,' by H. S. Gale and R. W. Richards. Both these papers are notable contributions to knowledge along lines that are of much present interest. Scarcely less valuable are some of the shorter articles which cover an unusually wide range. Many of them have already been given separate notice.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. C. Broadwater is at Los Angeles.

S. S. Sorrensen is in San Francisco.

Whitman Symmes is in San Francisco.

A. Roy Heise was in San Francisco last week.

George H. Garrey was at Los Angeles recently.

C. B. Lakenan has been visiting San Francisco.

J. A. Holmes spent Christmas in North Carolina.

S. F. Shaw is returning to New York from Costa Rica.

C. W. Purington has returned to London from St. Petersburg.

Thomas T. Read has been visiting the gold mines of France.

Huxley St. John Brooks has gone to the Philippine Islands.

E. V. Daveler has left Alameda, California, and is now at Garfield, Utah.

C. F. Tolman, Jr., has been appointed as Territorial Geologist of Arizona.

F. Oskar Martin has returned to San Francisco from the oilfields around Bakersfield.

George H. Gruss is in San Francisco from Gennessee Valley arranging to reopen the Gruss mine.

Henry S. Lewis, of Washington & Lewis, sailed for Brazil December 20 to be gone about four months.

John F. Armstrong has been nominated for another term as Register of the Land Office at Sacramento.

W. H. Blackburn, mine superintendent for the Tonopah M. Co., was in San Francisco, during Christmas.

Maurice H. Hare has been appointed manager and Western representative of the Idaho Company, Ltd., with offices at Spokane, Washington. The Idaho Company is operating two gold dredges at Pierce, Idaho.

David Cole has resigned as assistant general manager for the Cananea Consolidated Copper Co. to accept the position of manager of the Ray Consolidated Copper Co.'s business in Arizona, with headquarters at Hayden, Arizona.

C. S. Herzig and W. Murdoch Wiley have resigned as president and vice-president, respectively, of the Constant-Herzig Co. Mr. Herzig has taken over the mining contracts and will continue the business heretofore carried on by the mining department of the company.

OBITUARY

Joseph Gruss, a California pioneer who has worked mines in Plumas county, California, for thirty or more years, and also at Virginia City, Nevada, died at his home at Gennessee Valley, California, on December 21, at the age of 66 years. He was a native of Alsace.

Walter L. Pierce, who for 32 years had been connected with the Lidgerwood Manufacturing Co. and for 29 years its secretary and general manager, died suddenly of heart failure at his winter home in the Hotel St. Andrews, New York City, December 10. He was a son of John F. Pierce and was born at Dorchester, Massachusetts, on June 8, 1855. His parents survive him and he leaves a widow, a son, a brother, and a sister. Mr. Pierce's death was entirely unexpected. He had suffered for several years with nervous troubles, but by devoting much of his time to out-of-door pursuits he had apparently recovered. He was known to a wide circle of personal and business associates. He was remarkable as an organizer and so perfect was his work that no detail of the great business which grew up under his hand was neglected during his long absences from his desk while seeking health. Besides his connection with the Lidgerwood Mfg. Co. he was treasurer of the Hayward Co. and of the Gorton-Lidgerwood Company.

Market Reports

LOCAL METAL PRICES.

San Francisco, December 29.

Antimony	12—12¾c	Quicksilver (flask)	44½—45
